In this respect there is no difference except that for some curious reason those who practise aseptic surgery prefer to introduce a piece of gauze into their wounds as a drain instead of a drainage-tube. It is a fact that years ago Lord Lister not uncommonly employed capillary drainage in cases where he did not expect any great amount of discharge and he carried that out by introducing strands of catgut, horsehair, silkworm gut, &c., into one corner of the wound and pulling them out in a few days when the drainage was no longer necessary At the present time the exudation is much less and drainage is chiefly necessary only in cases where a cavity is left under the skin where the deep surfaces do not come together In such circumstances I can see no advantage whatever in the employment of gauze over a drainage tube. On the contrary, I think that the serum will be more readily carried away by a small tube. That, however, is purely a matter of fancy of the surgeon But the question is different when the drainage is carried out in suppurating cavities or in the case of septic wounds. In suppurating cavities the employment of gauze wicks is, to my mind, a very objectionable procedure The capillary drainage does not act when thick fluid like pus has to be removed and if gauze wicks are introduced into an abscess cavity they not only do not allow the pus to escape properly, at any rate not nearly so efficiently as a drainage tube would, but, becoming themselves soaked with the pus, they form septic foreign bodies which interfere with the healing of the wound and tend to keep up sepsis I have on several occasions had cases of septic wounds referred to me which would not heal and which I found were being drained by gauze wicks Healing was at once obtained on dilating the opening, removing the gauze wick, and introducing a drainage-tube

DRESSINGS

Surgery without Antiseptics	*Limited Use of Antiseptics*
The dressings consist of sterilised gauze or wool without any antiseptic in them. They are disinfected by heat in metal cases which are not opened till the material is required. No doubt the dressings so applied, provided the hands and skin are aseptic, are quite satisfactory from the aseptic point of view	The dressings consist of sterilised gauze or wool containing antiseptics stored up in them The method of sterilisation does not materially matter although I generally sterilise gauze in antiseptic solution The stored up antiseptics which one generally employs are the double cyanide of mercury and zinc, salicylic acid, &c These substances becoming mixed with the blood which escapes from the wound render it, for a time, at any rate, incapable of decomposition

I can see no logical reason whatever for giving up the use of antiseptic substances in the dressings. The antiseptics contained in the dressings, provided they are not of an irritating nature, can do no harm They cannot possibly affect the wound itself, through the closely stitched line of incision, while on the other hand they possess a great advantage over simple sterilised materials on the principles which led Lister to employ them. It is true that if the skin is aseptic and the wound is left aseptic and an aseptic dressing containing no antiseptic is applied decomposition will not occur so long as the discharge does not reach the surface, because the wool or gauze will act as a filter to the dust But so soon as the exudation reaches the surface of the dressing the bacteria will multiply in it rapidly spread up to the wound, and may then infect the skin stitches and from the skin stitches the wound itself. On the other hand, if the dressing contains an antiseptic material which, when dissolved in the blood and serum which ooze into the dressing prevents their undergoing at any rate a rapid decomposition the fact of the discharge coming through the dressing does not necessitate immediate change of the dressings, nor does the sepsis spread back to the wound. I see no reason whatever why the aseptic dressings applied over the wound should not contain an antiseptic which is unirritating to the skin and which adds such a great advantage to the dressing

It will thus be seen that after all there is comparatively little difference between the two methods employed but such differences as exist will help very much to correct unconscious errors on the part of the surgeon or his assistants, while the training of these assistants and of the nurses in these methods will, I believe, leave a very lasting and thorough impression on their minds

The Harveian Lectures

ON

FIBROIDS OF THE UTERUS AND ITS LIGAMENTS CONSIDERED FROM A CLINICAL AND SURGICAL STANDPOINT

Delivered before the Harveian Society of London on Nov 6th, 13th, and 20th, 1902,

BY ALBAN H G DORAN, F R C S ENG,

SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN MARYLEBONE ROAD, N W

LECTURE I

Delivered on Nov 6th 1902

MR. PRESIDENT AND GENTLEMEN,—In calling upon me to deliver these lectures you have conferred upon me an honour which I deeply appreciate and for which I most sincerely thank you. I have chosen for their subject certain questions of clinical and surgical interest in relation to fibro myoma of the uterus and its ligaments and my remarks will be mainly based on my own experience The different subjects will, no doubt, appear to you rather disconnected, but you will not expect me to deliver a systematic course of lectures on a subject so well known as the pathology, diagnosis, and treatment of uterine fibroid disease.

On the pathology of fibroids I need not say much, as we all know that a tumour of this class is essentially a myoma and contains more or less white fibrous tissue. The surgical anatomy of fibroids of the uterus and its ligaments is a matter of more pressing interest. Demonstrations of the anatomy of the triangles of the neck and of the structures concerned in hernia are very familiar to us. We who have to diagnose and to treat abdominal and pelvic tumours and are sometimes called upon to remove fibroids ought to make clear the anatomy of the parts concerned both in their origin and their development. On that account I shall first direct your attention to the surgical anatomy of the broad ligament and to the seat of origin of fibroid tumours associated with it. Next I shall turn to my own experience as to the treatment of the ovaries when the uterus is removed for fibroid diseases and say some words on the question of removal of the ovaries as a remedy in cases of that disease—an operation which still has distinguished advocates, as we learnt last summer at Manchester Then I will say something on some more or less purely clinical subjects in association with fibroid disease—namely, family history, hæmorrhage, absorption (another matter that was talked about at Manchester), ascites, necrotic changes "cup and ball" fibroids, disease of the appendages associated with fibroids, and, lastly, large vessels and the souffle in fibroids The concluding lecture will consist of my views and experience as to several surgical questions—namely, the management of capsules, adhesions in fibroid disease post-operative ileus in hysterectomy, rupture of the abdominal wound, and cancer of the stump I shall terminate with some observations on the danger of pushing impacted fibroids out of the pelvis You can now see beforehand that I shall not dwell on many subjects pertaining to uterine myoma and its treatment I shall omit all mention of those subjects, not only because I have not sufficient time to discuss them, but also because they have been so much talked about of late that some other matters, I mean those on which I intend to dwell, will probably interest you more or at the worst weary you less. For the most recent opinions about the more important subjects which I cannot discuss—namely, prognosis of fibroids, expectant treatment, and the merits of different operations—I refer you to the well-known writings of Dr F. H. Champneys,[1] Dr O J Cullingworth,[2] Dr M. A D Scharlieb [3] and Mr E Stanmore Bishop,[4] and to the recent discussion on total abdominal hysterectomy at the Manchester meeting of the British Medical Association.[5]

THE SURGICAL ANATOMY OF THE BROAD AND OVARIAN LIGAMENTS.

Since the establishment of pelvic and abdominal surgery a great deal has been written by Sir F. Treves, Mr. C. B Lockwood, and others about the folds of the peritoneum. In dealing with fibroids, clinically or surgically, we have specially to consider one fold, the broad ligament, and certain other bands, also dignified by the name of ligament, in its vicinity The more thoroughly we understand these folds and bands the better. The literature of the broad ligament is already very voluminous, but it has up to the present been mainly devoted to the question of burrowing cysts and extra uterine fœtal sacs, with which we are not directly concerned.[6] Still we make mistakes, or we may operate under conditions where diagnosis is uncertain, hence, whilst it is necessary for us to understand how fibroids may burrow into the folds of the broad ligament, it is also imperative for us to be aware what other kinds of tumour may be found insinuating themselves into these very same folds

We all know how the peritoneum is reflected over the Fallopian tube. Meeting below it, the layers lie close together until they reach the level of the ovary This reflexion is the upper portion of the broad ligament now universally known as the *mesosalpinx*. It contains the parovarium and an anastomosis of the uterine and ovarian arteries. Its connective tissue is scanty but loose, hence the Fallopian tube can be easily peeled off when its folds are opened up. The mesosalpinx is invaded by broad ligament cysts, by burrowing ovarian tumours, and also by many subserous fibroids of uterine origin that grow outwards Last month when removing a large fibroid uterus I was puzzled by a swelling in the left mesosalpinx of the size of an almond. I had to open the posterior layer before I could apply a ligature to the broad ligament Then I found a body like an extra-ovary, but Dr C H. J Lockyer pronounced it to be a pedunculated subserous uterine fibroid. Sessile fibroids of broad ligament origin do not, as a rule, develop in the mesosalpinx but rather in the mesometrium, presently to be described Hence the tube, mesosalpinx, and ovary often lie unaltered on the top of a big fibroid of the broad ligament—a most characteristic appearance and a useful guide to the operator I can show you, however, a specimen of a minute pedunculated fibroid attached to the posterior layer of the mesosalpinx. This specimen, to which I shall again refer at greater length, implies, I believe, that even a sessile fibroid independent of the uterus may develop in the mesosalpinx.

Owing to the small amount of connective tissue which it contains the mesosalpinx is not so much involved in para metritis as is the lower part of the broad ligament and it bears manipulation and ligatures much better It includes in its folds large lymphatic vessels which when obstructed, as frequently happens in cases of large uterine fibroids, appear as irregular yellow bullæ, sometimes concealing the Fallopian tube so as to confuse the relations of the tumour A branch of the ovarian artery which anastomoses with the uterine runs in the mesosalpinx close under the inner half of the tube. When the ligature slips from the inner part of a pedicle after removal of an ovary it is this artery which bleeds and in enucleating a uterine fibroid which has opened up the mesosalpinx the same vessel is cut or torn. It bleeds very sharply but is easily secured In concluding these observations about the mesosalpinx I must add that the operator should remember that when the fibroid burrows in the mesosalpinx the tube will lie stretched in the tumour, as in the case of parovarian cyst, whilst when it opens up only the lower part of the broad ligament, now to be described, the mesosalpinx and tube will project from the upper surface of the tumour

Vertical section through the broad ligament showing relations of mesosalpinx and mesometrium, as distinguished by Waldeyer

Posteriorly the ovary projects into the peritoneal cavity, anteriorly the round ligament, in its course from the uterus to the inguinal canal passes under the anterior layer of the broad ligament. Below the level of the ovary the broad ligament is best distinguished by the name *mesometrium* sanctioned by Waldeyer[7] The layers of the mesometrium as they descend part widely the gap being filled by the parametrium, part of the pelvic connective tissue. The anterior layer soon turns sharply upwards over the corresponding side of the bladder and pelvic wall, to become the parietal peritoneum of the abdomen. Hence this fold forms the lateral continuation of the utero vesical pouch. Its relation to the bladder is very important and is often greatly altered by fibroids which develop in the anterior part of the uterus and grow outwards. Broad ligament fibroids cause yet greater displacement of this fold Hence in operating on such cases the surgeon must make sure where the fundus of the bladder lies Even when the fold is normal the bladder may be round in abnormal relation to it. Tandler and Halban describe and figure a case where the bladder otherwise normal, was invested by the layers of one broad ligament.[8]

When a fibroid of the broad ligament or uterus grows forwards and upwards, displacing this fold, it not only draws up the bladder on its anterior aspect but also insinuates itself between the abdominal parietes and the parietal peritoneum The same happens when a pelvic cyst and when a tubo ligamentary pregnancy advances anteriorly, constituting the "anterior ligamentary pregnancy" of Taylor[9] In all cases the tumour lies in front of the peritoneal cavity The parietal peritoneum behind it protects it from infection from intestine

[8] Topographie des weiblichen Ureters, Plates xxxi. and xxxii.

I cannot understand why, in diagrams by Anderson and other anatomists of repute, drawings copied over and over again in text-books, the anterior layer of the broad ligament is represented as though it dipped down as low as the posterior We all know that the posterior layer, which below the ovary forms part of the mesometrium, passes deeply downwards into the pelvic cavity to form the anterior part of Douglas's pouch

Uterine and broad ligament fibroids sometimes grow backwards and upwards, displacing the posterior layer of the mesometrium. This complication, much more frequent than displacement of the anterior layer, brings the tumour into close relation with the ureter, vagina, and rectum, which may be adherent and therefore liable to damage at an operation. The neighbourhood of the rectum involves risk of infection, not so great, however, in the case of a fibroid as when an ovarian cyst or a tubo ligamentary pregnancy[10] displaces the posterior layer of the mesometrium. The "posterior ligamentary pregnancy" of Taylor usually becomes septic. But though fibroids in the same position are seldom infected ligatures applied to the capsule after their enucleation are especially liable to infection The mesometrium is the natural home, the seat of origin of most fibroids (fibro-myomata) of the broad ligament, which often do not open up the mesosalpinx even when they burrow extensively behind or in front of the peritoneum. Broad ligament cysts and ovarian tumours sometimes burrow in the mesometrium, after having already opened up the folds of the mesosalpinx, but I have noted instances where tumours of this class have, like a fibroid of the broad ligament, opened up the mesometrium alone, the tube and mesosalpinx lying free on the top of the tumour[11] A fibroid of the body of the uterus or of the cervix not rarely opens up the mesometrium. Enucleation in these circumstances is specially difficult. The parametrium, so abundant in the mesometrium, is subject to parametritis, either as the familiar "pelvic cellulitis" of childbed or as the inflammatory affection which sometimes follows hysterectomy through bruising of the tissues or from the irritation of ligatures The ureter and uterine vessels run in the lower part of the mesometrium. We know how the utero-sacral ligaments, which contain plain muscle fibres, form a kind of edge laterally to Douglas's pouch beneath them. They may cause the incarceration of a small ovarian tumour, a painful complication,[12] and I have found pedunculated fibroids springing from the back of the uterus similarly incarcerated, the uterus being drawn back I fancy, therefore, that they sometimes account for the pain caused by small tumours which occupy Douglas's pouch These ligaments may damage a backward displaced uterus by gripping it, but the amount of harm thus done is questionable A fibroid may develop in one of the utero-sacral ligaments

I now desire to turn special attention to a structure the importance of which has been underrated, I mean the *ovarian ligament* It is a fairly stout band of fibrous and plain muscular tissue which runs from the uterus to the ovary, causing a slight elevation of the posterior layer of the broad ligament. It is quite short, usually under an inch in length, but I have seen it nearly two inches long even when attached to a normal ovary The surgeon, for obvious reasons should remember that for practical—that is to say pedicle making—purposes it is short In cases of ovarian cyst, with which we are not directly concerned, it is elongated but in fibroid disease of the uterus it usually remains short. Histologically, and therefore anatomically, it is part of the uterus, it is a fibro muscular structure liable to become the seat of a fibroid, a true fibro-myoma. This specimen shows this form of tumour in a very early stage and more will be said presently about fibroma of this ligament. Such a growth is more than a pathological curiosity I shall have to speak of large ovarian ligament tumours. But such morbid growths are rare It is much more important for the surgeon to remember that a piece of detached ovarian tissue is occasionally to be detected in the ovarian ligament close to the uterus Operators of repute, such as Dr Murdoch Cameron and Mr Furneaux Jordan, still advocate oöphorectomy for the cure of fibroids, but I will show on the other hand that it is hard to remove all ovarian tissue in that operation owing to the nature of the ovarian ligament.

In July, 1901, I removed a large bleeding fibroid from a woman aged 41 years I sacrificed both ovaries as they were undergoing suspicious cystic degeneration. It happened, as is usually the case when an ovary is cystic, that the ovarian ligament was elongated, this was noted on both sides. Dr Lockyer examined the uterus and its appendages after the operation and found a distinct piece of ovarian tissue or "accessory ovary" in one ovarian ligament, close to the uterus. The patient recovered and the period was completely suppressed, not without very troublesome flushings. Had the case come under my care 15 years earlier I should probably have removed the ovaries alone Then the bleeding would almost certainly have continued as the "accessory ovary" would have lain in the pedicle. The occasional presence of ovarian tissue in the ovarian ligament and the natural shortness of that band need our serious consideration For it is, as a rule, impossible to remove the normal ovary entire with intent to check hæmorrhage from a fibroid or to prevent its further growth. The ovarian ligament is often hard to reach and if cut short after ligature there would be great risk of slipping of the silk and fatal hæmorrhage, whilst if cut long some ovarian tissue will be left behind and the object of the operation will be frustrated Whilst it is so difficult to remove all ovarian tissue with safety and to leave the fibroid uterus behind, there is no difficulty in taking away the ovaries entire at a hysterectomy They come away complete attached to the uterus by the ovarian ligaments. It is the outer, not the inner, attachments of the ovaries that are divided in that case The outer attachment of the ovary is the infundibulo-pelvic ligament, bearing the ovarian vessels, which does not contain detached portions of ovarian tissue and is readily divided at a point far external to the limits of the ovary Hence, when an ovary seems diseased, there need be no hesitation in removing it with the fibroid uterus Nor, on the other hand, is it difficult or dangerous to leave an ovary when the uterus is removed In that case the broad and ovarian ligaments are ligatured with the tube internal to the ovary and divided on the uterine side of the ligature which will hold well, the vessels on its distal side give no trouble after the big vascular uterus has been removed. Let it be noted how different is the case when the ovarian ligament is ligatured the ovary cut away, whilst the fibroid uterus full of large vessels is left behind.

Fibroid or Fibro myoma of the Broad Ligament

Fibroid tumour of the broad ligament has been shown by recent experience to be anatomically and surgically, though not pathologically and clinically, a disease distinct from fibroid of the body and cervix of the uterus. When of large proportions the proof that the tumour was not originally uterine may be contested. It happens, however, that several small broad ligament fibroids have been detected at operation or after death lying far from the uterus and separated from that organ by a wide tract of the parametric connective tissue. Streeter[13] removed a tumour of this kind weighing 10 ounces from the right broad ligament and I have recently reported a case[14] where I took away a large multilocular cyst of the left ovary and then found beneath it a very heavy little tumour, smooth, oval, and two and a quarter pounds in weight. It was enucleated with the greatest ease from the parametrium and was perfectly distinct from the uterus, it was made up of plain muscle cells and white fibrous tissue Vessels had to be secured in the parametrium, but no part of the uterus was wounded or ligatured and recovery was speedy

These broad ligament fibroids are really retro peritoneal. For clinical reasons I may note that Mr Marmaduke Sheild has reported a case of retro-peritoneal *fibroid* which he admits may have been of uterine origin.[15] It lay behind the mesentery, the position where large retro-peritoneal *lipomas* develop Now it happens that Sir Frederick Treves describes how he removed a *lipoma* from the broad ligament where we usually find *fibroids* of the kind which we are now considering[16] These rare conditions must be borne in mind when we attempt to diagnose a doubtful abdominal swelling

[14] Fibroid of Broad Ligament associated with an Ovarian Cyst Transactions of the Obstetrical Society of London vol xliii p 260. The specimen is in the Museum of the Royal College of Surgeons of England (Pathological Series A.4590, A a)

There remains one more subject of clinical and surgical importance in relation to fibroid of the broad ligament as a retro peritoneal tumour That class of morbid growth seems related to congenital displacement of the kidney Retro-peritoneal lipoma, properly so-called excluding lipoma of the omentum and broad ligament, is very rare. Yet in one case which occurred in my own operative practice[17] the right kidney lay on the brim of the pelvis its vessels being apparently derived from the common iliac artery and vein. Thus displacement of the kidney was detected in one out of about 30 reported cases of the most typical form of retro peritoneal tumour Turning to fibroid of the broad ligament, a less typical form, but pathologically retro-peritoneal, let it be noted that out of 39 cases which I have tabulated and published[18] in one there was a pelvic kidney The surgeon may as well remember that a kidney may lie much lower down than he suspects, so that he must be cautious while enucleating a fibroid of the broad ligament.

The surgical anatomy of a broad ligament fibroid is of much more importance to us than its pathology The tumour usually lies at first between the folds of the mesometrium. It is, as a rule, sessile, but it may be pedunculated. Whilst the mesometrium is always involved the mesosalpinx is seldom opened up, nor does this kind of tumour commonly originate between its folds which, unlike the mesometrium, include but little connective and muscular tissue. This specimen, to which I have already referred, shows that a broad ligament fibroid may be pedunculated and also that it may be connected with the mesosalpinx. Hence it is just possible that a sessile fibroid might originate in that part of the broad ligament. The specimen comes from the museum of the Royal College of Surgeons of England[19] and is thus described "A left broad ligament exhibiting a small pedunculated myoma, which is attached to the posterior surface of the mesosalpinx near the hilum of the ovary, *but unconnected with its ligament* From a middle-aged woman who had several pedunculated fibro-myomata attached to the serous surface of the fundus uteri.' It was found in the College stores. The fibroid is so small that its relations are evident—its pedicle has no connexion with the uterus, the ovary or the ovarian ligament The great majority of broad ligament fibroids, however are sessile tumours developing in the mesometrium The manner in which they open up that fold, push the intact mesosalpinx upwards, and come to lie in close relation with the bladder ureters, and rectum has been already explained when I spoke of the surgical anatomy of the mesometrium which must be thoroughly understood by all who attempt operations on pelvic tumours The perils of operative interference due to these relations are self evident. The rectum or ureters may be strongly adherent to the tumour and in all cases the parametric tissue is bruised. This tissue does not always tolerate ligatures, which are liable to infection from the neighbouring bowel The surgeon operating on a broad ligament fibroid must remember, on the other hand, that he has not to face other dangers inevitable when an equally large fibroid of the uterus itself is removed. In that case the cervix is often thick whilst the uterine cavity is dilated and lined with unhealthy endometrium. When the fibroid is confined to the broad ligament the uterus is usually small and flattened, it may be left behind as in the case where I removed a small tumour with an ovarian cyst or if advisable it may be removed with little addition to the risk of the operation

Such is the surgical anatomy of these tumours, but before speaking of treatment more must be said about the tumours themselves from a clinical standpoint They are proportionately much more frequent in young women than is any form of fibroid of the uterus and cervix proper According to my own tables 17 6 per cent. were observed in patients under 30 years of age. In one instance a fibroid of the broad ligament weighing over 18½ pounds was removed from a girl, aged 19 years, in another a tumour weighing 11 pounds was removed from a young woman, aged 22 years In a case where I operated the tumour was first observed already large when the patient was 23 years of age and it grew to enormous proportions in five years. On the other hand, fibroid of the broad ligament may appear after the menopause and, just as very big tumours have been found in young subjects, so very small growths of this class have been discovered in old women either at an operation or after death from some other disease. They may certainly take on growth after the menopause. It is interesting to find that, as in this kind of tumour, true fibroma of the ovary is not rarely seen in girlhood and in age[20] as well as in the mature This fact is of importance with respect to diagnosis.

We find anæmia not rarely in cases of fibroid of the broad ligament and it is of serious import otherwise than is the anæmic condition constant in bleeding uterine fibroids The anæmia in broad ligament fibroid is secondary to bad health. The impaired health may be due to the bulk of the tumour or to pressure effects on the vessels bowel, and ureters or to necrotic changes in the substance of the new growth which, just as when they occur in uterine fibroids, make the patient sickly When menorrhagia is present in a case of broad ligament fibroid there is probably a fibroid or polypus in the uterus as well.

The sessile fibroid of the broad ligament may attain a great size. As it is fixed it gives little trouble at first, it does not irritate the peritoneum by rolling about, nor does it worry the patient by setting up uterine hæmorrhage. Ascites is not a common complication. When it grows to its full proportions, however it is apt to cause grave pressure effects, whilst its maintenance is a tax on the patient. Ureteral obstruction may prove fatal even in cases where the tumour has not risen above the pelvic brim and has been overlooked during the patient's life (Gouget) Emaciation and anasarca of the lower extremities are extremely common. The larger tumours of this class range from 10 to over 40 pounds in weight.

The diagnosis of a fibroid of the broad ligament is not always difficult When the tumour is distinctly solid and sessile and the abdominal walls are thin the outline of the uterus on the anterior surface of the tumour can be defined or even seen. The uterus can sometimes be slid about laterally on the tumour The cervix lies high, close under the pubes, and is not rarely inaccessible.

In most cases diagnosis is difficult as the outline of the uterus cannot always be made out and the sound cannot in every case be passed owing to the elevation of the cervix and its compression against the pubes. Indeed it is not always easy to make out by dissection after the operation that the tumour has developed independently of the cervix. This section shows how doubtful the origin of the fibroid may be. I removed this tumour three years ago with satisfactory results One half is in the museum of St. Bartholomew's Hospital, the other in the museum of Charing Cross Hospital. I think that the tumour might have arisen in the parametrium behind the cervix. The practical importance of this question is clear—a broad ligament fibroid may sometimes be enucleated and the uterus spared, in fibroid of the cervix this cannot be done. It is a serious thing to remove the uterus of a young woman. The diagnosis of a soft or cystic sessile broad ligament fibroid is difficult even when the uterus can be clearly defined, it then closely resembles certain sessile tumours of ovarian or parovarian origin. Pedunculated fibroids of the broad ligament are usually impossible to diagnose from subserous fibroids attached to a uterus otherwise but little enlarged, or from fibroma of the ovary

The treatment of fibroid of the broad ligament should, I believe, be surgical in any case. A sessile tumour of this class is not likely to be harmless, after the fashion of many a fibroid uterus lying high above the pelvis and freely moveable. The dangers of operation steadily increase with the size of the tumour The removal of a sessile broad ligament fibroid of any size demands careful enucleation.

[18] Transactions of the Obstetrical Society of London vol. lxi., p 183, Case 7

[19] Museum of the Royal College of Surgeons of England (Pathological Series, No L. 4590)

[20] I have removed a fibroma of the ovary (weight 4 pounds 11 ounces) from a girl, aged 20 years, and another weighing 3 pounds from a woman, aged 52 years.

A small tumour of this class may be shelled out of the broad ligament, then, after the securing of all bleeding points and the uniting of the cut edges of the broad ligament by suture, the abdominal wound can be closed Thus the uterus is saved.

When the tumour is large enucleation is difficult. The necessary steps and precautions must be considered in detail Not only must asepsis be assured, but measures must be taken to anticipate or to minimise shock and hæmorrhage. No attempt should be made to draw the lower part of the tumour out of the pelvis by a sharp tug or by firm traction—such a manœuvre may cause laceration of the capsule and some of its vessels and damage to adherent rectum, bladder, or ureter The capsule must be divided first, but as the trunks of the ovarian and uterine vessels are very inaccessible, their preliminary ligature cannot always be effected Therefore the operator should never make a horizontal incision around the entire circumference of the tumour and then attempt rapid enucleation. Dangerous hæmorrhage would certainly ensue, however quickly and dexterously the enucleation be performed, even if the large vessels be caught on both sides, immediately after their division, by assistants Each vessel on the surface of the capsule must be secured by ligatures at two points about three inches apart. These ligatures can be passed under the vessels by means of blunt pointed pedicle needles Then the capsule should be divided horizontally between the ligatures for two or three inches The threads are drawn tight by assistants as the vessel is being divided. When all the vessels on the surface of the capsule have been thus secured the horizontal incisions can be joined so that the capsule is entirely divided. Then the lower part of the tumour can be enucleated The operator should never trust to pressure forceps when dividing the vessels on the capsule. The enucleation demands all the well known precautions required when a fibroid of the uterus proper is enucleated. Bladder, rectum, ureter, and other structures may be damaged by hurried, rough enucleation As for the vessels running into the tumour the pressure forceps applied at two points is useful at this stage. The vessel is divided between each forceps That instrument, unsafe when applied to vessels on the convex capsule before enucleation, is very convenient for securing vessels running across the space created by the separation of the tumour from its attachments to the capsule.

When the uterus is small and the tumour large it is advisable to amputate the body of the uterus above the cervix so as to take it away with the fibroid. The capsule may be closed as when the tumour is uterine Sometimes drainage or gauze-packing is safer, especially as regards certain after results of the operation. I intend to say more about the management of capsules in hysterectomy and allied operations

Of cases in my own practice one of the biggest, though by no means the heaviest, was observed in a woman, aged 44 years, who had borne three children, the youngest being 14 years of age She had suffered from swelling of the abdomen for over three years and it had recently increased in size The period appeared every three weeks and of late had lasted for about a week, but the show of blood was trifling Mr T A. Mulcahy of Portsmouth detected an elastic solid tumour which reached to the epigastrium and came down low in the pelvis I found that the os was drawn up too high to be reached, whilst the outline of the body of the uterus could plainly be felt above the pubes sliding on the tumour The catheter showed that the bladder was drawn up to the right groin I operated and managed to deliver the greater part of the tumour through a long abdominal wound The vessels on the capsule, much enlarged were tied in two places as described above. Then the capsule was divided horizontally and the fibroid enucleated, the uterus was removed, and the stump was treated intra peritoneally In this instance I was able to trim away much of the capsule, the edges of the remainder were sewn together The tumour was a very bulky fibro-myoma weighing 9 pounds 13 ounces, it had opened up the mesometrium, whilst the mesosalpinx lay intact with the tube and ovary on the top of the growth. The patient recovered. In this case the capsule, though thick, was not tensely stretched, and so its vessels were easily secured though enormously dilated. One big vein from the pampiniform plexus ran free from the infundibulo-pelvic ligament to the top of the tumour, the tissue connecting it to the broad ligament having been absorbed. This condition is more common in the dilated vessels of adherent omentum The capsule was easily pushed down so as to allow the bladder to fall to its normal level.

The largest fibroid which I have removed weighed 44½ pounds. It was in this instance that careful ligature of the vessels in the capsule, in the manner already described, proved so satisfactory Scarcely a drop of blood was lost. The patient gained flesh markedly after the operation, which took place in the autumn of 1898 One case, in a woman, aged 40 years, ended fatally The tumour was in part cystic and unfortunately had been tapped and drained three years before I operated. The cystic cavity discharged quantities of blood through the drainage track and was very septic, and small intestine adhered firmly to the surface of the tumour Pedunculated fibroids of the broad ligament are as a rule easily removed, but the pedicle may be thick and fleshy and great care is always needed to prevent hæmorrhage. Every bleeding point in the cut surface must be secured and the cut edges of the serous investment of the pedicle sewn over the raw surface When very thin, transfixion and ligature, as in ovariotomy, may be sufficient.

In these lectures I have endeavoured to confine my remarks as much as possible to my own experience. In relation, however, to the question of pedunculated fibroids independent of the uterus, I must here relate the instructive experience of Rosenstein,[21] who removed a fibro-myoma of the right utero-sacral ligament. The patient was 46 years of age The tumour was of "about the size of a man's head," tense, and freely moveable. It was diagnosed as a multilocular ovarian cyst. On one occasion, it is interesting to learn, the patient had a sharp attack of pain so that torsion of the pedicle was reasonably suspected At the operation the tumour was found to be perfectly free from the uterus but continuous with the middle of the right utero-sacral ligament by a distinct pedicle as thick as a lead pencil. It had no connexion with the Fallopian tube, ovary, ovarian ligament, or infundibulo pelvic ligament There was no difficulty in securing and dividing the pedicle which did not bear any large vessels No doubt other cases of fibroid of the utero-sacral ligament have been overlooked or rather mistaken for tumours of different origin

In conclusion, I have said enough to explain that a sessile broad ligament fibroid is a formidable kind of growth to remove and that its extirpation demands many precautions. I have already tabulated a series of operations on large tumours of this class[22] It is fair to say that enormous fibroids of the uterus itself may be successfully extirpated. Thus in Dr F Cole Madden's case, recently reported,[23] the tumour weighed 53 pounds. The patient was an Egyptian girl, aged 18 years—very young to be subject to fibroid. The tumour originated in the anterior wall of the uterus which was at once lifted out of the abdomen when the incision was made sufficiently large. Such a manœuvre is impossible in the case of a broad ligament tumour The patient was doing well according to the last report, six weeks after the operation.

FIBROID OF THE OVARIAN LIGAMENT

I will now say a few words about an interesting type of tumour closely related to the common uterine fibroid, although surgically it is akin to a pedunculated ovarian growth Many years ago I detected fibroid of the ovarian ligament in an incipient condition thus proving its possibility[24] Here is the specimen[25] and its relations are perfectly clear Microscopically it was composed of well formed plain muscular fibres mingled with white fibrous tissue. The tumour is plainly seen as a small spherical body about half an inch in diameter lying in the substance of the ovarian ligament midway between its uterine and ovarian extremities

Two years later I myself successfully operated on a tumour pathologically the same but over 16 pounds in weight.[26] Since then similar tumours have been removed by other operators Quite recently Dr Lockyer in examining two fibroid uteri which I had removed at the Samaritan Free Hospital for Women and Children found that in each there was a pedunculated fibroid of the ovarian ligament One of these tumours I exhibit this evening It is a firm, oval growth three inches in horizontal diameter, one and a half inches in vertical diameter, and two inches in antero posterior measurement The pedicle is very stout and about an inch in length. The base is attached to the uterine end of the ovarian ligament which appears to run from the pedicle to the ovary Being pedunculated the tumour was very moveable and as it was also heavy the severe pelvic pain from which the patient suffered seems to be comprehensible. I noted similar pain in a case of myoma of the ovary and in another of fibroid of an undeveloped cornu, in all these cases a small heavy, very moveable tumour hung down in the pelvis. This tumour may be instructively compared with the minute specimen which I have already demonstrated. It is only through a minute sample like the latter that we can feel sure of the origin of a tumour as big as the former

[26] Fibroma of the Ovary and Ovarian Ligament, Transactions of the Obstetrical Society of London vol xxxviii, 1886, p 164

I am not surprised that when a careful observer like Dr Lockyer studies fibroids he occasionally detects a growth of this kind connected with the ovarian ligament, for they are probably more frequent than is generally supposed. Still, as I have already observed, this other specimen[27] shows that a pedunculated fibroid may arise from the mesosalpinx quite independently of the ovarian ligament. The surgical importance of the distinction between a fibroid of the ovarian ligament and a pedunculated fibroid of the broad ligament is evident When the tumour is of purely broad ligament origin the pedicle alone may be secured by ligature and divided and the tube and ovary saved. This conservative practice is not always safe when the fibroid springs from the ovarian ligament, though Doléris was able to save the adjacent appendages when removing an ovarian ligament fibroid. It is bad surgery to remove an ovary in the case of a girl or a young wife if the operator can save the organ without risk Experience has shown that whilst a fibroid of the ovarian ligament manifestly demands removal its extirpation does not offer much difficulty to the surgeon. In my own case, notwithstanding its enormous bulk, the tumour was well pedunculated and I was able to secure its pedicle with ease, leaving the uterus I considered, on the other hand, that it was safer to remove the tube and ovary

Myoma of the ovary is probably derived from the muscular elements in the ovarian ligament and hence is anatomically uterine In a case where I operated it was clearly a process of the ligament which seemed to run in between it and a cystic growth which involved the whole of the ovary proper Though small, this myoma was exceedingly heavy[28] and caused pelvic pain so that inflammatory disease rather than a new growth was suspected. This kind of tumour is exceedingly rare and has nothing to do with fibroma of the ovary As in the case of fibroid of the ovarian ligament, removal of a myoma of the ovary is surgically an ovariotomy As a rule it proves very easy, for there are seldom adhesions, and the tumour, probably owing to its seat of origin never seems to burrow into the folds of the broad ligament

In concluding these observations on tumours of the ovarian ligament I must repeat what I remarked when demonstrating the anatomy of that structure. These rare fibroid tumours are of considerable interest, but it is much more important for us to remember that a piece of detached ovarian tissue is occasionally detected in the ovarian ligament quite separate from the ovary and sometimes very near the uterus. I further dwelt on the importance of these pieces of ovarian tissue in respect to the surgery of the ovaries.

THE ROUND LIGAMENT AND FIBROIDS.

When the uterus is distorted by fibroids the round ligament on one or both sides may undergo great hypertrophy This change I have observed even when it was but little stretched As a rule, of course, the hypertrophy is associated with stretching There is a familiar feature of surgical importance in respect to the hypertrophied round ligament. I refer to the great increase in size of its artery On that account the ligament should be secured with its artery separately during hysterectomy This practice is advisable whenever the uterine fibroid is large and vascular, even when the round ligament has escaped hypertrophy I have found the artery of that ligament very large in such circumstances When the removal of the fibroid cannot be effected quickly without risk one precaution essential in such circumstances is the ligature of the enlarged round ligament and its artery in two places followed at once by division. I know it to be dangerous to trust the distal end to a clamp Some surgeons object to tying the round ligament separately when it has not shared in the hypertrophy of the parts of the uterus adjacent to the fibroid. One ligature, to include the ovarian vessels and the round ligament, may be sufficient in these circumstances when the broad ligament is also narrow and not involved in the growth. I cannot think, however, that the round ligament artery is safely secured in this manner, more than once I have seen it spout, after the division of the ligatured broad ligament, though the ovarian vessels did not bleed. In one case, after closing the flaps over the stump, I detected rather free bleeding from the artery of one round ligament which I at once secured

The operator will always seek both round ligaments as landmarks when the precise seat of any pelvic tumour is uncertain. The round ligament is very useful when there is any doubt about a growth being tubal or uterine. As the text-books teach, it will spring from the outer side of a fibroid or hæmatometric tumour of a separate or ill-developed uterine cornu and will lie on the inner side of a tumour of the Fallopian tube or a tubal gestation sac. In the case of a tubal gestation sac the round ligament is always an excellent guide, whilst in oddly shaped fibroids springing from the cornu the relation of the round ligament may be far from clear, as in one case in my own practice[29] to which I shall again refer in the course of my observations on necrotic fibroids But in the majority of cases of fibroids in an undeveloped cornu the relation of the round ligament, usually much hypertrophied, is perfectly clear

Fibroid tumours of the round ligament itself are of much interest, but differ greatly in clinical characters from similar growths in the broad and ovarian ligaments. The latter are closely allied to uterine fibroids, whilst tumours of the round ligament lie in very different anatomical relations, so that it is not necessary for me to dwell upon them.[30]

FIBROID IN AN UNDEVELOPED CORNU AND CONDITIONS WHICH SIMULATE IT

Malformations of the uterine cornua are of much importance owing to the difficulties which they throw in the way of diagnosis and to the grave effects of the atresia which often accompanies them. Hence the bibliography of the subject is very extensive It begins with reliable records published before the nineteenth century and ends with valuable recent work such as Josephson's[31] scientific monograph An undeveloped cornu seems predisposed to the development of a fibroid growth in its substance and the author just quoted discusses at length this remarkable association of pathology and teratology In a short note on the Removal of a Fibroid from a Uterus Unicornis in a Parous Subject,[32] published three years ago, I summed up most of the records of cases of this condition reported by contemporary authorities in this country

Whenever we have to do with the abdomen and pelvis in a woman we must remember that deformities of the uterus are not exceedingly rare. When detected, we can never feel certain how far other parts of the genito-urinary tract may be normal or malformed. In the case of fibroid of an undeveloped cornu diagnosis may be easy, a thin band being detected on palpation between the uterus and the tumour, whilst the uterus, or rather half uterus, is small and strongly deflected to the side of the pelvis opposite to the new growth. In other cases especially when the half uterus is well developed through past pregnancies and lies centrally, diagnosis is often impossible. Again, a normal uterus has been suspected to be bicornute or to consist of one cornu and

most of us have come across doubtful cases of this kind Extreme lateral displacement of the body simulates uterus unicornis. The mistaking of a normal for a bicornute uterus is possible in certain conditions when the patient is pregnant Paul Bar[33] observed a case where in early pregnancy there seemed to be a soft tumour containing the fœtus and attached to a firm uterus, between the two there was a certain amount of mobility Yet the pregnancy proved to be perfectly normal. I relate this condition because the hard part of the uterus may be taken for a fibroid complicating pregnancy, I once witnessed the opening of the abdomen by an able operator who practised midwifery Cornual pregnancy with fibroid disease of the uterus was suspected. Yet the pregnancy was normal, the uterus was found to be less bilobed than it felt, it became quite regular when it emptied itself a few days later Bar reminds us that in these cases the ovum has become attached to the uterine wall close to the orifice of one tubal canal so that the adjacent part of the uterus develops at first much more rapidly than the remainder After the middle of pregnancy the rest of the uterus undergoes softening until the normal condition is attained. I am speaking, however, of fibroid in an undeveloped cornu rather than of cornual pregnancy, the above observations were simply made to warn us against diagnosing the coexistence of these two interesting conditions when it happens that neither is present. When, then this combination of two conditions each frequently associated with malformed cornu, is suspected we must watch the pregnancy for a month or two Still, diagnosis may be uncertain I recently operated on a most puzzling case where there was a bilobed tumour A fœtus lay in the right lobe which reached to the hypochondrium, whilst there was a loud souffle over the left as well as over the right tumour There was neither pain nor hæmorrhage and such is the rule in cornual as distinguished from tubal pregnancy I operated and, as you see, the left tumour proved to be a very vascular fibroid springing by a broad base from the posterior aspect of the inferior segment of the uterus to the left. The left ovarian vessels were rotated forwards by the growth of the tumour and accounted for the souffle. The bilobed tumour before it was exposed simulated in some respects pregnancy coincident in a normal uterine cavity and in a closed cornu, in other respects pregnancy in a normal uterine cavity and fibroid tumour in a closed cornu. Pregnancy of tubal origin was improbable, though Taylor and others have reported cases without a history of pain Without exploration diagnosis was impossible

There is much of interest in considering fibroid disease of a badly developed cornu independent of pregnancy I will put aside all cases of atresia where the fibroid becomes of secondary importance and only speak of cases where the opposite half of the uterus is normal. A small fibroid of this class lying loose in the pelvis may make itself known not so much by swelling and by the other conditions associated with a tumour as by pain and other symptoms indicating pelvic inflammation In this respect it may resemble a small heavy myoma of the ovary hanging down in Douglas's pouch. I happen to have had in my own operative practice a case of each of these forms of tumour where pain was the chief clinical symptom[34]

In my own case of fibroid in an undeveloped cornu the patient was 38 years old. She had been married for eight years and had been delivered five years before operation of a child who was then still living The forceps was used and after recovery she complained of falling of the womb Mr W O Aylward of Tunbridge Wells relieved this symptom by the aid of pessaries and detected a small, painful swelling in the hypogastrium The patient became pregnant again and aborted at the second month Then followed much pelvic pain without fever or high pulse Since the development of the painful swelling the period had been accompanied by sharp pain in the right iliac fossa and it recurred once after the miscarriage The patient then came under my care. I found the uterus markedly anteverted, the cervix was small but well formed. The sound passed three and a quarter inches. A freely moveable, hard, oval mass occupied the right fornix. It moved separately from the uterus On making an exploratory incision I was rather surprised to find no evidence of pelvic inflammation beyond a small adhesion which held down the left ovary The right appendages were not directly attached to the uterus but ran on to the outer surface of a firm tumour of the size of a hen's egg This tumour was connected internally with the uterus by a broad band, free above and continuous below with the pelvic peritoneum The cervix had no connexion with the tumour From the outer border of the anterior aspect of the tumour arose a very broad ribbon like structure which curved inwards and entered the inguinal canal. This structure was, of course, the round ligament The uterine artery, remarkably large and tortuous, ran up from below into the outer side of the tumour I performed a kind of enucleation by dividing the serous coat of the band after ligature of the right ovarian and uterine vessels, the tumour with the detached tube and ovary then came away There was a broad raw surface left on the divided band, the peritoneum was carefully sewn over it. A year later the patient became pregnant and was delivered of a well developed male child at term.

It is not clear why this little tumour caused pain, but as it was very heavy for its size it possibly set up the painful symptoms by dragging on surrounding structures. The remarkably thick round ligament has been noted in this anomaly before[35] The great size of the right uterine artery which supplied this little tumour was remarkable, the left artery which supplied the normal cornu, already once the seat of pregnancy was distinctly smaller The right ovarian artery and veins were not dilated These peculiarities about the blood supply of a tumour or hæmatometra in an ill developed cornu must be borne in mind by the operator He must make sure of the position of the uterine and ovarian arteries before dividing the pedicle. Simple transfixion and ligature of the pedicle as in ovariotomy would be dangerous, the two arteries should be ligatured before division of the pedicle

Lastly, I observed when speaking of the relations of the round ligament to a fibroid that in some cases of fibroid near the cornu those relations are not very clear

Oöphorectomy for Fibroids and its Teachings.

The removal of the ovaries for checking the hæmorrhage from a fibroid and reducing its growth was a very popular operation not many years ago but has recently fallen into disfavour Mr J Furneaux Jordan,[36] however, still defends it, under certain limitations, and Professor Murdoch Cameron created some surprise at the Manchester meeting of the British Medical Association by openly advocating this operation. "A new era,' said Professor Cameron,[37] "set in with the methods of Hegar and Tait, and notwithstanding current opinion against their methods, I desire emphatically to say that I have never met with a single bad symptom following the removal of the ovaries and tubes for fibroids when thought advisable, but on the contrary, I have found it highly beneficial in all cases operated on, and the patients themselves testify to the blessing they have enjoyed through its means. This has also been the experience of others in Glasgow" It would be interesting to know how this distinguished authority manages to remove the ovaries thoroughly without leaving a trace of ovarian tissue and yet without risk of slipping of ligatures owing to the necessary shortness of a pedicle of the ovarian ligament cut completely internal to the ovary I have taken some pains to demonstrate the anatomy of the ovarian ligament and noted that, short as it is, it may contain ovarian tissue. As a rule, when oöphorectomy for fibroid was largely practised the pedicle was cut too long and a piece of the ovary was to be seen on the distal side of the ligature. The piece of ovarian tissue sometimes underwent atrophy as in a case of my own which I recorded over eight years ago[38] The patient was 41 years of age, and very anæmic from menorrhagia due to a fibroid in the anterior wall of the uterus I reported that "owing to the shortness of the ovarian ligaments a minute portion of ovarian tissue was left on the distal side of the pedicle I rather feared at the time that the object of the operation would be frustrated." Yet the menopause was established permanently without any disagreeable symptoms I had several other similar lucky experiences and the same is the case with other operators Indeed, I am of opinion, on the ground of this experience, that cure was due in many such cases to some factor of which we are ignorant, the same may be said in explanation of Professor Cameron s brilliant results. A fibroid is capricious in its course and may cease to grow and to bleed spontaneously I am speaking, be it understood, solely of cases said to be suitable for oöphorectomy, cases where the fibroid grows near the fundus, nourished by the ovarian artery Yet I have had good results in several cases where even the cervix was involved, though with that condition failure is the rule My good, or, rather, lucky, results can hardly have been due to the removal of the ovaries alone. Indeed, the majority of patients did well for a year or so, then the bleeding returned or the tumour continued to grow In one case in my own practice[39] a strange result ensued great and permanent reduction in the size of the tumour occurred, yet the suppression of the catamenia was but partial. The "show" was accompanied by all the disagreeable symptoms of the menopause, and last autumn (10 years after the operation) the patient, then 48 years of age, saw the period three or four times yearly and suffered from occasional flushings.

[38] An address on the Treatment of Bleeding and other Uterine Fibroids by Removal of the Appendages Brit. Med Jour vol i 1894 p 1233 Case 1

A return and advance both of the bleeding and of the growth of the tumour seem, however, to have been the rule when oöphorectomy for fibroid was popular The reason seems to be evident the ovarian tissue on the distal side of the pedicle resumed its functions, for a time in abeyance owing to the organisation of lymph thrown across the groove formed by the ligature a condition well known in the pedicle after ovariotomy[40] In performing a hysterectomy in a case where oöphorectomy had failed I detected a small, flat button of ovarian tissue lying on the stump of the tube against the cornu of the uterus The operation itself was not without dangers—slipping of the ligature of the pedicle and thrombosis of a pelvic vessel or of one of the big veins of the lower extremity being not unknown. In anæmic cases the shock was often quite as great as after the removal of a big fibroid and I reported a fatal case in the address to which I recently referred Again the ovaries may be so placed in relation to a big tumour as to render their removal impossible. The hæmorrhage in some instances proved to be due to a polypus high up in the distorted uterine cavity and thus easily overlooked.

Mr Jordan believes that a hysterectomy always involves more shock and takes up more time than an oöphorectomy for fibroid disease[41] If so uncertain, however, for reasons which I have explained, hysterectomy must be a far better operation Mr Jordan s teaching may I admit, be advantageously followed under exceptional conditions. Thus in 1897 I removed the ovaries of a woman, aged 44 years, who was under Dr Travers Smith's treatment for hæmatemesis which had greatly reduced her health There was a small bleeding fibroid and I found the appendages springing from the uterus well below the tumour which was in the fundus Above all, the ovarian ligaments were long I speedily removed the ovaries and the "show" at once began to abate, ceasing altogether seven months after the operation. The patient's strength steadily increased, but unfortunately three months after the artificial menopause she died suddenly from perforation of the stomach. As far as the oöphorectomy is concerned this case was satisfactory, but a previous experience to which I have referred taught me that the operation may be followed by fatal shock without any clinical or post-mortem evidence of internal bleeding or sepsis

FALMOUTH DRAINAGE —At the meeting of the Falmouth Corporation held on Jan. 29th the general purposes committee reported that it was of opinion that the council could not carry out the contemplated drainage scheme owing to its cost. It was stated that the committee was unanimous in considering that the action of the Local Government Board in requiring the outfall to be carried considerably farther toward the east made the cost prohibitive.

ELECTRIC SHOCKS

BY DR S JELLINEK.

IN a very remarkable article which appeared in THE LANCET in 1902[1] Mr F B Aspinall gave his views regarding the action of the electrical current on the human body His reasons are strengthened by observation upon a large number of accident cases and by experiments carried out on the human body There is a boundary between the technical and the medical knowledge of electricity, and the physician wishing to treat the subject satisfactorily must understand the technical working of electricity as well as the scientific, otherwise the solving of certain questions is impossible. As I myself have been studying atmospheric and technical electricity concerning their effects on animals I wish to add a few remarks to the article published in THE LANCET[2]

While I agree with Mr Aspinall on a great many points, on some important questions I am of another opinion. As to his first question "Is everyone equally susceptible to an electric shock?' I agree with him that susceptibility depends upon the individual I would add to the above that women and children show less resistance and are therefore more endangered by a current than are males, also that the point of entrance is of importance, mucous surfaces being much more dangerous than the skin.

Secondly, Mr Aspinall asks "Is a person suffering from disease more likely to be fatally injured by an electric shock than a person in good health?" and states that the question is difficult to answer I believe, however, that all diseases which lower skin resistance—e.g, Basedow's disease, diseases of the heart and kidneys, and some skin diseases—predispose to accident from electric shock. The effect of an electric current is, as Mr Aspinall observed, dependent upon the resistance of the skin. *Cæteris paribus* the skin offers the chief resistance, for example, we find that on measuring the resistance of the hand when dry the galvanometer (Universalgalvanometer von Siemens) indicates 50 000 ohms, but after wetting the hand with a solution of sodium chloride that the number of ohms is reduced to 500—100 times less than in the first condition. The importance of this becomes clear to us when we remember Ohm's law $C = \frac{E}{R}$ which shows that in the above case the person in the first condition would receive 100 times less ampères than in the second. A person suffering from heart disease is much more sensitive to the electric current than when the heart is normal. Here I will remark that in my opinion the lesions of the central nervous system produced by electricity are of the greatest importance, of these lesions I will speak later

Very interesting and highly important are the cases described by Mr Aspinall with reference to his third question ' Does the physiological condition which a person is in at the time a shock is received make any difference?" With regard to the first case which he mentions I believe that the greater part of the current was carried away by the heavy flannel shirt, which was drenched with perspiration, and that only a small part of the current passed through the body His description of the effect of the electric current on sleeping persons deserves special consideration, Mr Aspinall being the first to observe that otherwise dangerous currents are harmless to sleeping persons In the cases which he mentions it is certain that the persons suffered an electric shock from the fact that severe burns were found on the bodies Unfortunately, I have never had the opportunity of observing the effect of electricity on sleeping persons I wish to call attention to the similarity which exists between the above mentioned cases and the following experiments[3] which I have carried out on animals

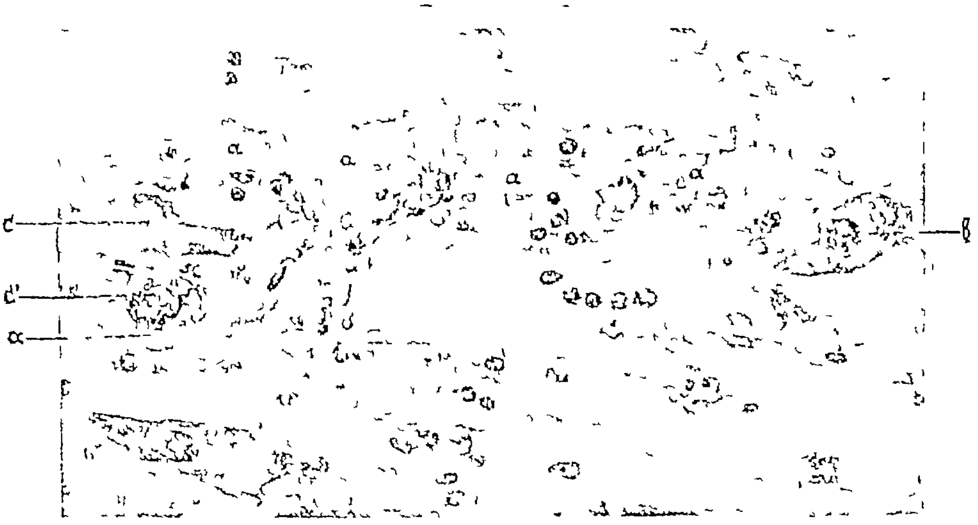
---

[1] THE LANCET March 8th 1902, p 660

[2] A part of my observations and experiments have appeared in the following publications Beobachtungen an Elektricitätsarbeiten Wiener Klinische Wochenschrift No ii., 1900 Blitzschlag und Elektrische Hochspannung Wiener Klinische Wochenschrift Nos xxviii. and xxix. 1901 Vorrichtungen zur Verhütung von Unglücksfällen durch die Elektrischen Oberleitungen eine neue Isolirzange Oesterreich Sanitätswes, No xxxvii 1901 Elektrizität und Chloroformnarkose Wiener Klinische Wochenschrift No xlv 1901 Animalische Effecte der Elektrizität Wiener Klinische Wochenschrift Nos xvi and xvii 1902 Histologische Veränderungen im Menschlichen und Thierischen Gehirn und Ruckenmark theils als Blitz theils als Elektrizität Hoorkstrom wirkung Virchow s Archiv Band clxx 1902 Zur Klinik der durch Atmospherische und Technische Electrizität verursachten Gesundheitsstörungen Vortrag am Elektrischen Congress in Bern 1902 and Elektrisches Unfallwesen Zeitschrift für klinische Medizin zu erscheinen)

If a rabbit be subjected to a high tension interrupted current, with one pole in the mouth and the other in the rectum, it will be either immediately killed or paralysed for several hours in all four extremities, or a spasmus nutans may be present, or it may cease to eat and soon die from starvation, &c. If, however, a rabbit be deeply chloroformed so that it does not react to the severest mechanical irritations—for example, the insertion of a needle into the spinal cord—and while in this condition be subjected to the same high tension interrupted current as in the previously described case for only a fraction of a second a remarkable change takes place the rabbit assumes a position of opisthotonos, then tries to rise falls down again cries out, opens its mouth, and in a few minutes the animal appears to have perfectly recovered The control animal that was narcotised at the same time but not subjected to the current died. *The high tension interrupted current thereby proves itself to be not only harmless for rabbits during narcosis but is even life saving* I have not yet finished my experiments with the other narcotics. I mention the above experiment only because our observations appear to agree, that is, an otherwise fatal current has no injurious effect on animals in an insensible condition (sleep or narcosis)

FIG 1



Represents the hæmorrhage and alteration of ganglion cells from the spinal cord of a man killed by an electric current of 1000-volt tension *a* Hæmorrhage *b* Unaltered cell *c.* Destroyed cell *c'* Nucleus and nucleolus from destroyed cell lying in the hæmorrhage

I agree with Mr Aspinall in the statement that "the path" which the current takes through the body is important. The left side seems to be more sensitive than the right, but this fact is not due, in my opinion to any injury to the valves of the heart but rather to the effect on the ganglia of the heart. Owing to the necessity of brevity I cannot further discuss this important question. I will only remark that the current is most dangerous when it is brought to bear on the heart and nervous system in greatest density I have made pathological sections from the hearts of both men and animals but have never discovered anything abnormal.

Another question on which I differ from Mr Aspinall is the following "Does the question of contact made, and whether burning takes place or not, have any effect upon a person's chance of being killed?" I have made similar experiments to measure the resistance and I agree with Mr Aspinall that the area and completeness of the contact bear an exact relation to the resistance. When, however, Mr Aspinall asserts that the burning "is a wonderful provision of nature to protect us against fatal shocks, as the burning not only numbs the nerves and thus prevents us from feeling but will also be found to increase the resistance, thus preventing the current passing," I must protest, as I have found by repeated experiments that the resistance is lowered after burns of the body In my publication "Animalische Effecte der Elektrizität" I have fully explained three different methods of measuring the resistance, by which I can prove that the longer the tissue is exposed to currents from the main the less the resistance becomes. I have demonstrated the above on a portion of the sciatic nerve by first measuring the resistance which proved to be 120,000 ohms. I then subjected it to a current from the main of 300 volts. I immediately again measured the resistance and found that it had sunk to 70,000 ohms and was reduced by 1000 ohms for every second of time that it was exposed. After the experiments the resistance began to increase The anatomical alteration of the tissue appears to be the cause of the reduction of the resistance

This fact of reduction of resistance through currents from the main, which is sometimes very great, is of great importance to the physicians of accident insurance companies. In explanation of the above I would refer to the technical formula for the work performed by a current A (ampère), × V (volt) × *t* (time) This formula is true only in estimating the power of a current in driving machinery, in men, however, it does not hold true, as resistance constantly decreases through every second of contact, thereby increasing the ampèrage, thus the *t* has not the function of a simple algebraic expression In consideration of the above changes which my experiments have proved we must admit that the time (*t*) during which a person is exposed to the current is important for two reasons first, that *t* has the same value as in the above formula, secondly, owing to the decrease of resistance and increase of ampèrage the effect is in five seconds not only five times greater but considerably more.

In regard to the sixth question "Can a person receive a fatal shock without giving the 'cry,' and also can he speak after receiving a fatal shock?" I quite agree with Mr. Aspinall that the cry is "a rapid drawing in of the breath," that it does not occur in every case, and that this cry is due to sudden contraction of the diaphragm In those cases, however where the current is not dangerous and the victim is not rendered insensible but is held to the machine by muscular contraction, the cry is not involuntary

Mr Aspinall has discussed very fully the seventh question "Is an alternating or a direct current shock more likely to prove fatal?" From my experiments and observations I have found that both alternating and direct currents from 500 to 600 volts are dangerous and currents of tension of 1000 volts without exception are fatal. With a low tension of from 100 to 200 volts the alternating current is much more disagreeable, and this difference I can prove by measuring the pressure of the blood current by means of the tonometer of Professor Gärtner of Vienna. Almost without exception the blood pressure is changed. After exposure to the direct current it increases from 10 to 20 millimetres, while, following the alternating current, a reduction of pressure of

from 10 to 15 millimetres is present, thereby proving that the direct current has an action different from the alternating current when using a current of a tension of from 100 to 200 volts. With higher tensions I have not experimented Mr Aspinall is of the opinion that a direct current seems to paralyse the victim at once "whilst an alternating current shock seems to draw him closer and to tie his body as far as possible into a knot. My experiments and observations on men and animals show that the effect of both currents is to produce a severe spasm of all the muscles during the action of the current. I myself have touched a wire carrying a direct current of 500 volts tension and was immediately repulsed I have also observed and read of cases where the contact was made with the whole hand gripping the wire, and in these cases the person is always held fast. The most peculiar phenomenon is the pushing away of the persons. Professor S Exner of Vienna thinks that it is possibly caused by the sudden strong contraction of the entire musculature.

Mr Aspinall's eighth question is "Cannot medical men give us a more certain method of ascertaining whether a man is dead or not?" As to whether the heart function is entirely lost it is difficult even for the physician to decide. In my experiments on animals I have observed that several hours after apparent death they show signs of life For this reason I believe that the attempts at restoration after shock should be continued for hours or until some certain sign of death appears

I wish to call special attention to the importance of the ninth question 'Cannot something more be done to help those who receive a shock?" Mr Aspinall asks if it would be advantageous to "hold the body for a few seconds head downwards at an angle of 45°, thus flushing the brain and stimulating its action?" Flushing the brain" in particular I would warn against The method of reasoning by which Mr Aspinall arrives at this conclusion is very plausible, but the fact is that there are direct contra indications to this treatment. During the microscopical examination of pathological preparations taken from three men and six animals that were killed by electricity I was successful in finding that the capillaries of the central nervous system were torn and that blood had escaped and permeated the surrounding nervous substance These hæmorrhages were found almost without exception in the grey substance of the brain and cord. I also discovered an alteration of the ganglion-cells.[5] These changes are illustrated by Figs. 1, 2, and 3. Such a hæmorrhage is not necessarily fatal, but it is very probable that the above method of flushing the brain would lead to secondary hæmorrhage and therefore result fatally In my opinion it would be better to perform venesection. Artificial respiration should be continued for hours, massage of the abdomen and of the region of the heart, placing the patient in a hot bath, subcutaneous injections of ether, camphor, or strychnine, should also be carried out. I believe that many of those victims who are pronounced dead could be revived by taking the necessary time and trouble.

In conclusion, I wish to remark that Mr Aspinall's observations are of the greatest interest to physicians and that these very difficult problems regarding the action of electricity in the human body can only be solved through the combined and harmonious efforts of both physicians and engineers

[5] The etiology and character of the above described pathological alterations I have fully described in Virchow's Archiv October 1902 Band clxx Heft 1 p 44

LENGTH OF STAY OF SCARLET FEVER PATIENTS IN THE METROPOLITAN ASYLUMS BOARD'S HOSPITALS.—At a meeting of the Metropolitan Asylums Board on Jan 24th the hospitals committee reported that it had had under consideration a letter from the Metropolitan Branch of the Incorporated Society of Medical Officers of Health, drawing attention to the length of stay of scarlet fever patients in the hospitals of the Board as compared with that of patients in some of the provincial hospitals, and suggesting that a conference should be arranged on that subject between the Board's medical superintendents and the medical officers of health The committee stated that it had discussed that suggestion and as a result of its consideration had informed the society that it saw no objection to such a conference but that it did not appear to it that for the holding of such a conference there was any necessity for the official sanction of the Board or of the hospitals committee, adding that, so far as it could see, there was nothing to prevent two bodies of medical men meeting together to discuss a purely medical question. The Board agreed with the action of the committee

THE VALUE OF BLOOD EXAMINATIONS AS AN AID TO DIAGNOSIS AND PROGNOSIS[1]

BY J H. BRYANT, M.D , F R C P LOND ,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO GUY'S HOSPITAL

I HAVE been greatly interested in blood examinations for some time and am much impressed with the important information which can be derived from this method of investigation. I have therefore ventured to hope that a few remarks on the value of this form of clinical examination as an aid to diagnosis and prognosis will be of interest. During the last few years the number of workers in this field of clinical pathology has increased enormously and some very important papers and text-books have been published which deal with the subject and I would mention in particular the works of Ehrlich and Lazarus, Cabot and Ewing A further impetus has been given to this fascinating form of research by a greater perfection in the methods, by the introduction of more reliable instruments, and by a simplification of the manner of fixing and staining films for microscopical examination. For many years it has been customary both in hospital and general practice to examine the urine of every patient when first coming under observation. The tendency at the present time is certainly in hospital practice to make also an examination of the blood of every in patient, and in this respect the Johns Hopkins Hospital at Baltimore has been the pioneer, for every patient admitted to this institution, irrespectively of the diagnosis, has the blood examined in a routine manner At Guy's Hospital many more examinations are made than hitherto, in the clinical wards which I have recently had under my charge the blood of every patient was examined as soon as possible after admission. It would be a matter of impossibility for a busy medical man engaged in general practice to use this aid to diagnosis in anything like a systematic manner on account of the length of time it requires to conduct a satisfactory examination of this kind The technique is also a stumbling block, this, however, can easily be overcome by a little practice The scope of this paper must necessarily be small as the subject is so large, but I shall endeavour by reference to a few of my cases to draw your attention to some important and practical points and to give you an indication of the class of case in which a clinical examination of the blood is likely to prove of value.

There are several different methods of examining the blood, but I shall confine myself to a consideration of the following (1) the estimation of the number of red and white blood corpuscles and the percentage amount of hæmoglobin, (2) an examination of stained blood films in order to determine the relative proportion of different kinds of leucocytes, the form and character of the red blood corpuscles, and the presence or absence of protozoa and micro organisms, (3) the determination of the agglutinating power of the blood on certain bacilli—e g, in typhoid fever and Malta fever, and (4) the bacteriological examination of the blood.

Before considering these methods of examination I will first of all remind you of the condition of the blood in health and of the abnormal corpuscles which may be found in disease. The normal number of red blood corpuscles per cubic millimetre is from 5,000,000 to 6,000,000 in men and about 4,500 000 in women The average number of white blood corpuscles per cubic millimetre is about 8000 in adults and 10,000 in children The varieties of white corpuscles and their relative proportions in health are polymorphonuclear leucocytes, from 70 to 72 per cent., lymphocytes, from 22 to 25 per cent., large mononuclear leucocytes 1 per cent., eosinophiles, from 2 to 4 per cent., transitional, from 2 to 3 per cent., and mast cells, 0 5 per cent. Myelocytes are present in leukæmia but not in normal blood In health the red cells are more or less uniform in shape and size but in disease there may be smaller or larger forms and also nucleated cells of various sizes. The varieties of red corpuscles found are normal red blood corpuscles, small red blood corpuscles (microcytes) large red blood corpuscles (macrocytes), normal sized nucleated cells (normoblasts), small sized nucleated cells (microblasts), large sized nucleated cells (megaloblasts), enormous sized nucleated cells (gigantoblasts), cells which stain irregularly (polychromatophilic), and cells altered in shape (poikilocytes) The estimation of the number of the red and white blood corpuscles is best accomplished by the Thoma Zeiss hæmocytometer and of the hæmoglobin by Haldane's hæmoglobinometer The technique of the making and staining of films, the estimation of the agglutinating power of the blood on certain bacilli, and the bacteriological examination I will endeavour to explain at the end of my remarks should time permit.

I *What can be learnt from an estimation of the number of red blood corpuscles and of the amount of hæmoglobin.*—An examination of the blood is often necessary before an accurate diagnosis can be made, when anæmia is the most important and prominent indication of the patient being ill. Anæmia may be due to a deficiency of red blood corpuscles or of hæmoglobin or of both. It is of great importance to note the relation between the reduction in the number of the red blood corpuscles and of the percentage amount of hæmoglobin and it is at once obvious that there are three possible types of change which may occur—viz. 1 A much greater reduction in the percentage amount of hæmoglobin than in the number of red blood corpuscles—viz. with 3,500;000 (e.g, 70 per cent.) red blood corpuscles to the cubic millimetre 25 per cent of hæmoglobin—the colour index being therefore considerably under 1. This is the chlorotic type of blood. 2. A very great diminution in the number of red blood corpuscles with a relative higher percentage of hæmoglobin—e.g, 1,000 000 (i.e, 20 per cent) red blood corpuscles to the cubic millimetre with 25 per cent of hæmoglobin—the colour index being therefore above 1. This is the pernicious anæmia type. 3 An equal or approximately corresponding reduction of the number of red blood corpuscles and percentage amount of hæmoglobin—e.g, with 2,500,000 (i.e., 50 per cent.) blood corpuscles to the cubic millimetre 45 per cent. of hæmoglobin—the colour index being just under 1. This is the type of a secondary anæmia. If the anæmia, however, is very severe it may approach nearer to the chlorotic type. It is by carefully noting the relationship between the number of red blood corpuscles and the percentage amount of hæmoglobin that a secondary anæmia can be distinguished from a primary anæmia when the cause is not apparent after a careful physical examination. A primary anæmia is a form of anæmia in which the cause is either unknown or there is no sufficient pathological change found to account for it. A secondary anæmia may be defined as a form of anæmia which is the result of some recognisable pathological change or lesion Chlorosis and pernicious anæmia are classed as primary anæmias Secondary anæmia may be caused by an actual loss of blood, from diminished and defective nutrition, and from increased consumption or loss of albumins, it may therefore result from severe hæmorrhages, from wasting diseases such as phthisis, cancer, &c, from syphilis, malaria, plumbism, intestinal parasites, and many other causes

I will now tell you about three patients who were sent to me as cases of pernicious anæmia in order to have the diagnosis confirmed or refuted by an examination of their blood

CASE 1.—A man, aged 40 years, was brought to me for pernicious anæmia. He had been ill for three months and had been unable to work His friends kept asking him why he was looking so pale and this was the first indication of the commencement of his illness. He had always enjoyed good health before. He had never had anything to do with lead He had gradually been getting weaker and during the last three months had lost over a stone in weight. He had not vomited or passed any blood. He had had no pain. There had been neither sickness nor diarrhœa. He was intensely anæmic. His pulse was 124 and he was rather dyspnœic. The examination of the blood showed red blood corpuscles 3 750 000, white blood corpuscles, 12,000, and hæmoglobin, 25 per cent—a chlorotic type of blood the colour index being under 0 5, which at once showed that he was not suffering from pernicious anæmia, and further it was not likely that his condition could be explained by chlorosis for this disease is most unusual—in fact, almost unheard of—in men of this age. I therefore concluded that it was a secondary anæmia and after making a careful, systematic, physical examination found a tumour in the right lumbar region. It was tender, did not extend far back into the loin, was not connected with the liver, and was resonant on percussion. The urine was healthy A diagnosis of carcinoma of the ascending colon was made which was subsequently verified by an operation and later by a post-mortem examination. This tumour gave rise to no local symptoms and was not discovered until the blood examination had proved that he was not suffering from pernicious anæmia, for which he had been treated.

---

[1] A paper read before the West Kent Medico-Chirurgical Society

CASE 2.—A man, aged 72 years, was brought to me for cough and bladder trouble. He had enjoyed good health until about six months before when he was noticed to be ailing He had suffered from bleeding hæmorrhoids, frequent micturition, and looseness of the bowels. He had lost flesh and his appearance suggested malignant disease. A careful and systematic physical examination was made but nothing abnormal was found to account for his weakness. His urine was normal. A few weeks afterwards he went to the Riviera, became weaker and very anæmic, and consulted a medical man who felt what he considered to be some enlargement of the spleen. He diagnosed pernicious anæmia and treated him with arsenic. I saw him again about four and a half months after first seeing him, and found that he was intensely anæmic and very much like a case of pernicious anæmia in appearance. A blood examination showed 4,500 000 red blood corpuscles, 5000 white blood corpuscles and 38 per cent. hæmoglobin—i.e., a chlorotic type of blood, the colour index being low, which at once excluded pernicious anæmia. A careful physical examination of the abdomen and of the tumour which was stated to be the spleen showed that it was more characteristic of an enlargement of the kidney or of a carcinoma of the colon. The former was considered to be most likely and a subsequent post-mortem examination proved it to be so.

These two cases illustrate the marked changes which take place in the blood as a result of carcinoma, but in both, the hæmoglobin index was remarkably low Case 2 also is an example of what is usually found in most cases of malignant disease—viz., that in the early stages the anæmia is not a prominent symptom. The blood in carcinoma has a closer resemblance to chlorosis than any other form of secondary anæmia, for the hæmoglobin index is always low In Osler and McCrae's monograph on malignant disease of the stomach, accurate blood counts were made in 59 cases the average number of red blood corpuscles was 3,712,186 (over 70 per cent.), the average percentage of hæmoglobin was 49 9, and the average number of white blood corpuscles was under 8000 to the cubic millimetre

CASE 3.—The patient was a man, aged about 40 years, who was sent to me on account of his extreme anæmia and weakness, pernicious anæmia having been diagnosed. He had all the typical symptoms of anæmia and the general appearance of pernicious anæmia. For a long time he had been suffering from bleeding hæmorrhoids. The only abnormal condition, discovered after a careful physical examination, was the presence of large bleeding internal hæmorrhoids The blood examination showed that he was not suffering from pernicious anæmia, for he had 2,950 000 red blood corpuscles, 12,187 white blood corpuscles, and 22 per cent. of hæmoglobin, which indicated a marked secondary anæmia of the chlorotic type The hæmorrhoids were treated by operation and the loss of blood stopped. Alginate of iron and arsenic were administered and after a few months he appeared to be perfectly well.

CASE 4 *Chlorosis.*—A girl, aged 18 years, was admitted into Guy's Hospital under my care for syncopal attacks, restlessness, and vomiting She had led a sedentary life and had been under extremely bad hygienic conditions. There was no history of any loss of blood. She had suffered from amenorrhœa and constipation for some time. She was intensely anæmic and very short of breath on admission. There were loud hæmic bruits at the base of the heart and a well marked venous hum in the neck. There were no physical signs or symptoms of disease of the lungs, liver, spleen, kidneys, or any of the abdominal viscera or of organic disease of the heart. A diagnosis of chlorosis was made and confirmed by the blood examination. There were 3,000,000 (67 per cent.) red blood corpuscles, 16 000 white blood corpuscles, and 25 per cent of hæmoglobin. The leucocytosis was caused by some suppuration under the nail of her big toe. She was treated by rest in bed and with ten grain doses of alginate of iron three times a day Three and a half weeks afterwards a blood count showed rapid improvement. The red blood corpuscles numbered 3 875,000 and the percentage of hæmoglobin was 50 per cent.

The blood in chlorosis in marked cases is very pale and it rapidly coagulates. The average number of red blood corpuscles is 4,000 000 to the cubic millimetre when the patient first comes under observation and it is extremely rare to find a case with the red blood corpuscles as low as 1,000 000 The leucocytes are not increased A blood examination alone will therefore not be sufficient to differentiate a case of chlorosis from a severe secondary anæmia. The diagnosis can only be correctly made when the result of the blood examination and the physical examination of the patient are considered together If leucocytosis is present and the polymorphonuclear cells are increased chlorosis without any complications can be excluded. In the case of chlorosis alluded to above the leucocytosis was accounted for by the suppuration under the big toe-nail.

CASE 5 *Pernicious anæmia.*—A woman, aged 50 years, was under my care for pernicious anæmia, the third occasion on which she had been in the hospital for treatment for this condition. She was first admitted on April 4th, 1901, for vomiting and palpitation. She had been under treatment for acute dyspepsia. She had not been able to do any work since October, 1900, and her chief symptom had been vomiting On admission she was markedly anæmic and her skin had a peculiar light yellowish tint. A blood examination showed 650 000 (13 per cent) red blood corpuscles to the cubic millimetre and 26 per cent. of hæmoglobin, the colour index therefore being 2, which is exceptionally high , there were 7000 leucocytes to the cubic millimetre She was treated with liquor arsenicalis, five minims three times a day Her mouth was in a very septic condition and there was well marked pyorrhœa alveolaris. Cultures were taken and various bacilli, cocci, and streptococci were found. On the 13th she was ordered one-minim keratin coated tabloids of creasote and later was treated with injections of anti-streptococcic serum She improved and on May 14th the blood showed 1,800,000 red blood corpuscles and 41 per cent. of hæmoglobin. She left the hospital much improved but was readmitted two months afterwards. She was intensely anæmic, the blood count being red blood corpuscles 750 000 and hæmoglobin 20 per cent. The blood film showed poikilocytosis and a number of normoblasts. She gradually became worse and died. At the post-mortem examination the only abnormal change which was found was an excess of iron in the liver

This was a typical case of pernicious anæmia. The blood in this disease is pale and watery and coagulates slowly There is a remarkable decrease in the number of the red corpuscles. The average in 52 cases examined by Cabot was 1,200 000 per cubic millimetre and the lowest count which has been recorded is in a case reported by Quincke in which only 143,000 red blood corpuscles to the cubic millimetre were present. The examination of a blood film shows in this disease a large proportion of macrocytes and the presence of nucleated red blood corpuscles. The diagnosis must rest on the small number of red blood corpuscles, the relatively higher percentage of hæmoglobin, and the presence of a large number of macrocytes and megaloblasts. The bad prognostic signs in this disease are an extreme reduction of the red cells—e.g , to 600,000 per cubic millimetre,—a high colour index, the presence of a large number of megaloblasts, and an increase in the number of lymphocytes

II. *Some practical points to be learnt from an estimation of the number and of a differential count of the various forms of leucocytes* —The average number of white corpuscles in healthy adults is 8000 to the cubic millimetre. Certain physiological and pathological states are associated with an increase of leucocytes, whereas in other diseases the number of these cells may be diminished. Leucocytosis is the term used to indicate the former condition and leucopenia the latter. The degree of leucocytosis varies between very wide limits, from 10,000 or 12,000 to 1,000 000 or more cells per cubic millimetre, and cases have been recorded in which the white have equalled and even exceeded the red in number Leucocytosis may be caused by a large number of conditions and it may be either physiological or pathological. Physiological leucocytosis occurs in the newly born, after digestion, during pregnancy after parturition, after cold baths, violent exercise, massage, &c. Pathological leucocytosis may occur after hæmorrhage, as a result of inflammatory and septic conditions, from certain toxic states, in malignant disease, as a result of certain therapeutic

THE VALUE OF BLOOD EXAMINATIONS AS AN AID TO DIAGNOSIS AND PROGNOSIS[1]

BY J H. BRYANT, M.D, F R C P LOND,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO GUY'S HOSPITAL.

I HAVE been greatly interested in blood examinations for some time and am much impressed with the important information which can be derived from this method of investigation I have therefore ventured to hope that a few remarks on the value of this form of clinical examination as an aid to diagnosis and prognosis will be of interest. During the last few years the number of workers in this field of clinical pathology has increased enormously and some very important papers and text-books have been published which deal with the subject and I would mention in particular the works of Ehrlich and Lazarus, Cabot and Ewing A further impetus has been given to this fascinating form of research by a greater perfection in the methods, by the introduction of more reliable instruments, and by a simplification of the manner of fixing and staining films for microscopical examination. For many years it has been customary both in hospital and general practice to examine the urine of every patient when first coming under observation. It would be a matter of impossibility for a busy medical man engaged in general practice to use this aid to diagnosis in anything like a systematic manner on account of the length of time it requires to conduct a satisfactory examination of this kind The technique is also a stumbling block, this, however, can easily be overcome by a little practice The scope of this paper must necessarily be small as the subject is so large, but I shall endeavour by reference to a few of my cases to draw your attention to some important and practical points and to give you an indication of the class of case in which a clinical examination of the blood is likely to prove of value.

There are several different methods of examining the blood, but I shall confine myself to a consideration of the following (1) the estimation of the number of red and white blood corpuscles and the percentage amount of hæmoglobin, (2) an examination of stained blood films in order to determine the relative proportion of different kinds of leucocytes, the form and character of the red blood corpuscles, and the presence or absence of protozoa and micro-organisms, (3) the determination of the agglutinating power of the blood on certain bacilli—e g, in typhoid fever and Malta fever, and (4) the bacteriological examination of the blood.

Before considering these methods of examination I will first of all remind you of the condition of the blood in health and of the abnormal corpuscles which may be found in disease. The normal number of red blood corpuscles per cubic millimetre is from 5,000,000 to 6,000,000 in men and about 4,500 000 in women The average number of white blood corpuscles per cubic millimetre is about 8000 in adults and 10,000 in children The varieties of white corpuscles and their relative proportions in health are polymorphonuclear leucocytes, from 70 to 72 per cent., lymphocytes, from 22 to 25 per cent., large mononuclear leucocytes, 1 per cent., eosinophiles, from 2 to 4 per cent., transitional from 2 to 3 per cent., and mast cells, 0 5 per cent. Myelocytes are present in leukæmia but not in normal blood In health, the red cells are more or less uniform in shape and size, but in disease there may be smaller or larger forms and also nucleated cells of various sizes. The varieties of red corpuscles found are normal red blood corpuscles, small red blood corpuscles (microcytes) large red blood corpuscles (macrocytes), normal sized nucleated cells (normoblasts), small sized nucleated cells (microblasts), large-sized nucleated cells (megaloblasts), enormous sized nucleated cells (giantoblasts), cells which stain irregularly (polychromatophilic), and cells altered in shape (poikilocytes) The estimation of the number of the red and white blood corpuscles is best accomplished by the Thoma Zeiss hæmocytometer and of the hæmoglobin by Haldane's hæmoglobinometer The technique of the making and staining of films, the estimation of the agglutinating power of the blood on certain bacilli, and the bacteriological examination I will endeavour to explain at the end of my remarks should time permit.

I. *What can be learnt from an estimation of the number of red blood corpuscles and of the amount of hæmoglobin.*—An examination of the blood is often necessary before an accurate diagnosis can be made, when anæmia is the most important and prominent indication of the patient being ill. Anæmia may be due to a deficiency of red blood corpuscles or of hæmoglobin or of both. It is of great importance to note the relation between the reduction in the number of the red blood corpuscles and of the percentage amount of hæmoglobin and it is at once obvious that there are three possible types of change which may occur—viz. 1 A much greater reduction in the percentage amount of hæmoglobin than in the number of red blood corpuscles—viz. with 3,500,000 (e.g, 70 per cent.) red blood corpuscles to the cubic millimetre 25 per cent of hæmoglobin—the colour index being therefore considerably under 1. This is the chlorotic type of blood. 2. A very great diminution in the number of red blood corpuscles with a relative higher percentage of hæmoglobin—e.g, 1,000 000 (i.e, 20 per cent) red blood corpuscles to the cubic millimetre with 25 per cent of hæmoglobin—the colour index being therefore above 1. This is the pernicious anæmia type. 3. An equal or approximately corresponding reduction of the number of red blood corpuscles and percentage amount of hæmoglobin—e.g, with 2,500,000 (i.e., 50 per cent.) blood corpuscles to the cubic millimetre 45 per cent. of hæmoglobin—the colour index being just under 1. This is the type of a secondary anæmia. If the anæmia, however, is very severe it may approach nearer to the chlorotic type. It is by carefully noting the relationship between the number of red blood corpuscles and the percentage amount of hæmoglobin that a secondary anæmia can be distinguished from a primary anæmia when the cause is not apparent after a careful physical examination A primary anæmia is a form of anæmia in which the cause is either unknown or there is no sufficient pathological change found to account for it. A secondary anæmia may be defined as a form of anæmia which is the result of some recognisable pathological change or lesion. Chlorosis and pernicious anæmia are classed as primary anæmias Secondary anæmia may be caused by an actual loss of blood, from diminished and defective nutrition, and from increased consumption or loss of albumins, it may therefore result from severe hæmorrhages, from wasting diseases such as phthisis, cancer, &c, from syphilis, malaria, plumbism, intestinal parasites, and many other causes

I will now tell you about three patients who were sent to me as cases of pernicious anæmia in order to have the diagnosis confirmed or refuted by an examination of their blood

CASE 1.—A man, aged 40 years, was brought to me for pernicious anæmia. He had been ill for three months and had been unable to work His friends kept asking him why he was looking so pale and this was the first indication of the commencement of his illness He had always enjoyed good health before He had never had anything to do with lead He had gradually been getting weaker and during the last three months had lost over a stone in weight. He had not vomited or passed any blood He had no pain. There had been neither sickness nor diarrhœa. He was intensely anæmic His pulse was 124 and he was rather dyspnœic. The examination of the blood showed red blood corpuscles, 3,750 000, white blood corpuscles, 12,000, and hæmoglobin, 25 per cent—a chlorotic type of blood the colour index being under 0 5, which at once showed that he was not suffering from pernicious anæmia, and further it was not likely that his condition could be explained by chlorosis for this disease is most unusual—in fact, almost unheard of—in men of this age. I therefore concluded that it was a secondary anæmia, and after making a careful, systematic, physical examination found a tumour in the right lumbar region. It was tender, puscles can be found a very short time after the initial or and when the case ends by crisis the leucocytes do not l to their normal number with the temperature but take o or three days to do so When the temperature falls by is the leucocytosis falls with it and the normal number the cubic millimetre is, as a rule, recorded when the nperature remains normal. If there is a difficulty in king a diagnosis, the presence of leucocytosis would point pneumonia and exclude typhoid fever, influenza, and laria. If the case is obviously pneumonia and the patient very ill with a considerable area of lung involved, an sence of, or a very slight degree of, leucocytosis is an tremely grave prognostic sign. If the leucocytosis remains r several days after the temperature has fallen, and then a rther rise of temperature and an increase in the number leucocytes occur a relapse or empyema is indicated. Dr A. Gaitskell has recently been working in the wards of ay's Hospital on this subject and has published his results [2]

---

[1] A paper read before the West Kent Medico-Chirurgical Society

CASE 11.—The patient was a woman, aged 24 years, ffering from pneumonia. Dr Gaitskell found no increase leucocytes, the whole of the patient's left lung was con lidated, and in spite of the fact that her condition appeared be satisfactory a bad prognosis was given and was con rmed by the death of the patient on the eighth day

If pneumonia complicates typhoid fever an absence of ucocytosis or even a leucopenia does not necessarily mean bad prognosis A case of this nature was investigated by r Gaitskell

CASE 12.—The patient was a boy, aged nine years, whose eucocytes did not rise above 10,937 per cubic millimetre fter the first examination, on account of the absence of eucocytosis, a bad prognosis was given, but two days after rards a typical Durham (so-called Widal) reaction was ob ained, and the absence of leucocytosis being thus explained more favourable prognosis was given and justified by the oy's subsequent recovery

In typhoid fever the most important characteristic of the lood is an absence of leucocytosis and in the later weeks of he disease the presence of a leucopenia. The differential ount shows a progressive increase in the number of the ymphocytes with a corresponding decrease in the poly norphonuclear cells I have already pointed out that liseases characterised by suppuration are usually associated with a polymorphonuclear leucocytosis, so that an absence f leucocytosis would be a point in favour of typhoid fever and much against appendicitis, perinephric abscess, hepatic abscess, suppurative pylephlebitis, and other forms of intra abdominal suppuration, and it would also be against pneumonia.

CASE 13.—There has recently been a case of pyosalpinx in the hospital admitted for typhoid fever The absence of a positive Durham reaction and the presence of a marked leucocytosis helped to exclude typhoid fever and to indicate the presence of intra abdominal suppuration.

CASE 14.—A few weeks ago a patient under the care of Dr E. C Perry (who has kindly allowed me to mention this case) suffering from a typical attack of typhoid fever suddenly, on the fifteenth day of the disease, complained of severe abdominal pain, became collapsed, and appeared to be suffering from hæmorrhage or perforation The question of hæmorrhage was soon decided The specific gravity of the blood was found to be 1053, which indicated that there had been no serious loss of blood The red corpuscles were enumerated and found to be 3,760,000 per cubic millimetre, which also pointed to the same conclusion. This view was subsequently confirmed by no blood being passed per rectum It seemed much more likely that perforation had occurred On the previous day he had bitten off and swallowed the bulb of a thermometer which had injudiciously been placed in his mouth, it was in the third week of the disease, he had suffered from marked twitching of his hands which is said to denote that the ulceration was deep, the abdomen was full, rigid, and tender, and there was very little movement during respiration. The pulse was 128 and running in character The leucocytes were counted and found to number 8250 per cubic millimetre, a result which was very much against perforation having occurred. It was decided not to operate at once, but that laparotomy should be performed if there was an ingravescent leucocytosis, so a leucocyte count was therefore made every hour for the next 12 hours, the number being found to vary between 7500 and 9000 per cubic millimetre. From a consideration of the result of these blood counts taken together with the improving condition of the pulse it was decided not to operate, and the decision has been justified by his complete recovery

Malaria is a disease which is often confounded with typhoid fever, for in addition to pyrexia and other symptoms it is also characterised by an absence of leucocytosis. This difficulty does not often arise in this country unless patients have returned to it from a malarial district abroad The presence of the malarial parasite in the blood is the absolute and decisive test of the presence of malaria Tuberculosis cannot be distinguished from typhoid fever by a blood examination alone

Eosinophilia.—I have alluded to a disease in which the lymphocytes are enormously increased, to conditions characterised by an increase in the polymorphonuclear cells, and to another disease in which a large number of myelocytes are present I shall now say a few words about eosinophile cells The examination of a blood film and the finding of a large number of eosinophiles were instrumental in clearing up a very difficult case.

CASE 15.—The patient was a man, aged 25 years, who was admitted under my care for cough and attacks of dyspnœa. He had been invalided home from India. He had been seen by a physician who had diagnosed aneurysm and in consequence of this diagnosis he would have had to retire from his appointment. He was sent to me by Dr O S Pantin of Douglas who had diagnosed asthma. I failed to find any positive evidence of aneurysm and an examination under the x rays did not show any sign of this condition. A blood examination showed red blood corpuscles, 6,587,500, white blood corpuscles, 10,625, and hæmoglobin, 90 per cent. The differential count showed 24 per cent. polymorphonuclear cells, 59 per cent eosinophiles, 4 per cent. large lymphocytes, and 13 per cent. small lymphocytes Eosinophilia in asthma has been noted by many observers and its occurrence in this case was undoubtedly an important diagnostic sign in favour of this disease. The blood examination saved this patient from compulsory retirement.

Eosinophilia occurs in a good many diseases and especially in certain skin diseases—viz., pemphigus, eczema, sclerodermia, psoriasis, urticaria, &c , also in some of the diseases due to animal parasites—e.g , bilharzia hæmatobia, ankylostomum duodenale, &c.

Malaria is a disease which cannot be diagnosed with certainty until the parasites have been demonstrated in the red blood corpuscles and this is best accomplished by staining thin films with carbol thionin blue, eosin and methylene blue, or with Jenner stain Not only can malaria be diagnosed but the particular kind of parasite may be demonstrated and from the examination of a blood film the type of fever predicted The demonstration of the parasite is sufficient to distinguish it from other febrile diseases The spirillum of relapsing fever may be demonstrated by means of blood films Streptococci, pneumococci, typhoid bacilli, and other organisms are not usually found in stained films and their presence cannot be relied on as an aid to diagnosis.

III. *What can be learnt from the addition of blood serum to living motile cultures of certain bacilli* —The diagnosis of two diseases—viz., typhoid fever and Malta fever—may be very materially helped by noting the agglutinating power of the serum of a patient suffering from either of these diseases on recent motile cultures of their respective bacilli If a few cubic centimetres of blood serum from a patient suffering from typhoid fever are added to a recent actively motile broth culture of the bacillus typhosus the bacilli are precipitated in flakes leaving the upper part of the fluid clear, and if the sediment is examined under the microscope the bacilli will be found to be no longer motile but to be agglutinated into compact non motile masses The agglutinating power of the blood is tested by mixing some blood serum with a recent culture of the typhoid bacillus and examining the mixture under the microscope Authorities differ as to the degree of dilution and the time limit which constitute a positive reaction It is customary in the Bacteriological Laboratory at Guy's Hospital to use a 50 per cent, 5 per cent., and 0 5 per cent. dilution and the reaction is not considered positive unless clumping and immobility of the bacilli occur with the 1 in 200 dilution within half an hour Examinations made before the eleventh day of the disease with a negative result are of little value. That the result of the reaction is of great value influences, and in leukæmia. I shall confine my remarks to a few of the pathological conditions characterised by leucocytosis When estimating the particular significance of the presence of leucocytosis in any given case it is not only necessary to find the number of white blood corpuscles per cubic millimetre, but also to know the percentage number of each variety of cell, which can be most satisfactorily ascertained by the examination of a stained film. The following case illustrates the importance of attending to these points.

---

[2] Guy's Hospital Reports vol. lvii.

CASE 6—A woman, aged 56 years, came to my out-patients' department on account of a painful swelling in her left side below the ribs About a month before, as she was feeling ill and on account of the pain, she consulted her medical attendant who, after examining her, told her she was suffering from an enlargement of her left kidney When I examined her abdomen I found a large tumour occupying the left hypochondriac, left lumbar, and left half of the umbilical region It was tender and had a fairly well defined, hard, rounded edge extending downwards from the right costal margin towards the umbilicus and reaching to a point about half an inch below it. It yielded a dull percussion note which was continuous in front with the usual area of normal spleen dulness. It could be felt to extend well into the loin, so that from the physical signs it was difficult to say whether the tumour was splenic or renal I examined a fresh specimen of blood under the microscope and found an enormous increase in the white blood corpuscles, for there appeared to be about one white to seven or eight red and this suggested a diagnosis of spleno medullary leukæmia. She was admitted into the hospital and a few days afterwards a more careful examination of the blood showed a moderate leucocytosis with the polymorphonuclear cells predominating and no myelocytes A subsequent post-mortem examination showed that the tumour was a perinephritic abscess, secondary to a calculous pyonephrosis which had discharged into the colon

This case shows that a too hasty opinion must not be expressed before a satisfactory blood examination has been made. In cases of enlargement of the spleen a correct diagnosis cannot be made until the blood has been examined and this applies in particular to enormous enlargements of the spleen such as may be due to spleno-medullary leukæmia, chronic malaria, splenic anæmia, and spleno-megalic cirrhosis

CASE 7—A man, aged 30 years, came to my out-patients' department for anæmia, shortness of breath, and enlargement of the abdomen He was markedly anæmic His abdomen was distended and the spleen was enormously enlarged. It was found that the blood was pale and that it clotted very readily There were 3,000,000 red blood corpuscles, and 300 000 white blood corpuscles to the cubic millimetre, and 42 per cent. of hæmoglobin. The differential count of the leucocytes showed—polymorphonuclear cells, 49 per cent , myelocytes, 44 per cent. , lymphocytes, 4 per cent. , and eosinophiles, 3 per cent. The large percentage of myelocytes pointed with certainty to a diagnosis of spleno medullary leukæmia.

CASE 8.—A girl, aged 23 years, was sent to the hospital for enlargement of the abdomen which was thought to be due to an ovarian tumour A careful physical examination revealed enormous enlargement of the spleen which was considered to be due to spleno medullary leukæmia. The blood examination showed a diminution in the number of red blood corpuscles and of the amount of hæmoglobin, but no leucocytosis. As she was not suffering from any intercurrent disease and had not been abroad her condition was considered to be due to either splenic anæmia or splenomegalic cirrhosis, and certainly not to spleno-medullary leukæmia. A few days afterwards she died from hæmatemesis and at the post-mortem examination the enlargement of the spleen was found to have been due to cirrhosis of the liver

The chief characteristics of the blood in spleno medullary leukæmia are a reduction in the number of red blood corpuscles to about 3,000,000 per cubic millimetre, and an enormous increase of the white cells to between 200,000 and 500,000, of which over 30 per cent. are usually myelocytes.

In cases of enlargement of the glands, especially if associated with enlargement of the spleen, a blood examination is necessary before a correct diagnosis can be made. The disease which can, in particular, be diagnosed by this means is lymphatic leukæmia

CASE 9—A boy, aged 15 years, had no illness until a week before he was admitted into the hospital when he felt pains in the neck, axillæ, and groins, and on the following day he noticed lumps which quickly enlarged to the size found when he was admitted On admission enlarged glands were found in the submaxillary, submental, cervical, axillary, sub-occipital, and inguinal regions A diagnosis of acute tuberculosis of the glands or of acute lymphadenoma was made. A blood count showed that the correct diagnosis was lymphatic leukæmia, for there were 3,800,000 red blood corpuscles and 43,750 white corpuscles, of which 95 6 per cent were lymphocytes Subsequent examinations showed a great increase in the number of white cells to 116,875 and 126,000 He died from hæmoptysis.

The chief characteristics of lymphatic leukæmia are therefore enlargement of the glands with or without enlargement of the spleen, but, when it is enlarged, never reaching the enormous size it does in spleno medullary leukæmia The red blood corpuscles are diminished in number as a rule to about 3,000,000 to the cubic millimetre , the percentage of hæmoglobin is reduced as in spleno-medullary leukæmia. The white blood corpuscles are much increased, but do not as a rule exceed 150,000 to the cubic millimetre and the percentage of the lymphocytes is enormously increased, on an average to about 96 per cent. Such an enormous lymphocytosis as this serves to distinguish it from lymphadenoma and other diseases characterised by enlargement of the glands or spleen.

In suppurative and inflammatory conditions a leucocytosis may occur which does not often exceed 50,000 to the cubic millimetre A differential count usually shows that the polymorphonuclear cells are in excess and may amount to 90 per cent. of the leucocytes. Klein has described a case of hæmorrhagic septicæmia in which 40 per cent. of eosinophiles were found in the blood This occurrence of leucocytosis as a result of suppuration has a very important bearing on diagnosis, treatment, and prognosis, and is well exemplified in cases of appendicitis Last year I had two male patients admitted on the same day suffering from appendicitis and each had a tumour in the right iliac fossa. After a careful physical examination and a consideration of the state of the abdomen and of the general condition of the patients I came to the conclusion that in one the tumour would subside and he would get well without an operation and in the other that a surgical procedure would be necessary I had a blood examination made and found in the former 8500 leucocytes and in the latter 25,000 leucocytes. I asked my surgical colleague, Mr L. A. Dunn, to see the two cases, and he decided to operate at once on the patient with the marked leucocytosis and to leave the other He found an abscess and drained it and the other patient recovered without an operation. I do not mean to claim that a blood examination will tell you when to operate and when not to operate, but it will be an additional indication should the state of the abdomen and the general condition of the patient point to the advisability of immediate surgical interference.

CASE 10—Three months ago I hurriedly had to make a journey to the west of England to see one of my sisters who was suffering from a typical attack of appendicitis and it was left to me to decide whether she should be immediately operated on or not. Her pulse was 100, the temperature was 103° F , and there was a large tender swelling in the right iliac region From a physical examination alone it was almost impossible to say whether pus was present or not I made a blood examination and found between 11,000 and 12,000 leucocytes and on the strength of this I decided to defer the question of operation. The opinion thus formed was justified by her recovery, the tumour gradually diminishing in size until it finally disappeared I mention this case to emphasise further my opinion of the importance of blood examination in such cases

Cabot's experience is that a marked leucocytosis—i.e., over 25 000—usually means a large abscess or peritonitis. A catarrhal appendicitis rarely causes leucocytosis. Very mild cases and very severe cases may show no leucocytosis, so that, as I have already stated, a blood examination must not be relied on alone as an indication of the pathological changes which have taken place or as an absolute guide to operation With regard to differential diagnosis if there is a difficulty in determining whether a patient is suffering from appendicitis or typhoid fever a leucocytosis would practically exclude typhoid fever In pneumonia blood examinations are of very great importance both from the point of view of diagnosis and prognosis, for leucocytosis is a constant accompaniment of it, very mild and fatal cases being excepted. The increase in the number of white blood irreducible and gangrenous; the others were reducible, some with ease and some with more or less difficulty. One case (Case 1) was evidently quite beyond surgical treatment and died shortly after admission into the hospital. Of the five successful cases four were quite young children, being five months, six months, six months, and eight months old respectively. In no case was inflation or injection of fluid by the rectum attempted; the futility of thus wasting valuable time has been amply demonstrated, whilst the cases relieved completely by these methods are few and problematical. Whilst surgical registrar of the London Hospital I collected for Mr. Frederick Eve the results of 53 cases many of which had been either inflated or injected and in every case laparotomy had to be subsequently performed. Injection or inflation is undesirable for two reasons, first, because it might actually rupture the gut by the pressure exerted, and secondly because it is likely to reduce the intussusception up to the last inch or two and then to cease to act. This last portion is always the most difficult to reduce manually; again, this last inch or two gives rise to a comparatively small mass which may easily be overlooked on abdominal palpation. The condition is supposed to be completely relieved only to return again when the pressure of fluid or air is relaxed.

In text-books on intestinal obstruction mention is made of the physical condition of the children as a factor in the production of intussusception. Some authors consider that it is more often found in the ill fed and delicate. My experience at the London Hospital has been exactly the reverse—in nearly every case which I have observed there during the last seven years one has been struck by the good physique and general lustiness of the patient. One might suggest, therefore, that too vigorous peristalsis is responsible for the condition rather than an atonic state of the gut wall; probably in many cases careless feeding with indigestible food has been the exciting factor. That so many cases should occur in the week following Christmas day may also point in the same direction. With regard to the actual operative technique practised in those five cases which recovered in three cases a median incision was made below the umbilicus whilst in the other two the abdomen was opened in the lower part of the right semilunar line. In those cases in which the sausage like tumour could be made out in the descending colon, left iliac region, or per rectum a median incision was made. In each case an attempt was made to reduce the gut by simply introducing two fingers of one hand within the abdomen and manipulating the gut with the other hand on the abdominal wall. Complete reduction by this method was found impossible; in every case the cæcum, colon and ileo-cæcal junction had to be brought up to the wound and manipulated outside the abdominal cavity. The difficulty of complete reduction by the first method was, I found, due to the mobility of the cæcum, a distinct mesocæcum being present in nearly every case. Great care was taken to prevent prolapse of gut through the abdominal wound and the colon which was exposed was protected carefully by hot sponges wrung out of boiled water.

I feel sure that the keynote of success in operating on these cases is "rapidity." The time occupied from the actual incision of the abdominal wall to the tying of the last suture was noted. It did not exceed 15 minutes in each case—one took 10 and another 12 minutes. The usual precautions were taken to prevent shock, the limbs and chest were incased in cotton-wool, and the operations were performed on a hot-water pillow.

With regard to the after treatment, the feeding of these children was commenced almost as soon as they had recovered from the anæsthetic effects; this in the absence of vomiting is an essential point. In many cases children have been constantly sick for two or perhaps three days before admission to hospital. They are much exhausted, and to withhold nourishment, as is sometimes practised for a further six or eight hours after operation may just prove sufficient to turn the balance in the wrong direction. Opium was given to each child if any restlessness was present. Two-minim doses of nepenthe acted well; in one case a small hypodermic injection of morphia was necessary owing to persistent vomiting after anæsthesia. In two cases—viz., Cases 2 and 5—a rise of temperature (104° and 106° F. respectively) followed within a few hours of operation; this was doubtless due to sudden toxic absorption from the lymphatic area of the inflamed and damaged gut. Saline fluid injected per rectum in the latter case appeared to have a very beneficial effect. Case 7, in which resection was performed with a fatal result, was a particularly interesting and unusual one. The site of the intussusception commenced only five feet from the duodenum; it was an enteric form—i.e., small gut within small gut—and curiously enough the lower part was invaginated into the upper—i.e., a retrograde or ascending intussusception. This was verified at the post-mortem examination. In addition to the actual intussusception of the gut the mesentery had been twisted on its axis so giving rise to gangrene of about two and a half feet of intestine. The following are brief notes of the cases.

Case 1.—The patient was a male, aged five months, who was admitted into the London Hospital on Dec. 26th, 1902, with the following history. The illness began three days previously with severe pain in the abdomen; blood was then noticed in the motions; the child had vomited constantly up to the day of admission. His condition on admission was as follows. He was a well nourished child, evidently much collapsed; his eyes were sunken and he had the abdominal facies. The pulse was feeble and not countable. The abdomen was generally much distended; no definite tumour was made out on palpation. No tumour was felt per rectum but some blood and slime were present on the examining finger. The child's condition was considered to be too bad for operative treatment and he died four hours after admission. At the post-mortem examination an ileo-cæcal intussusception was found which had entered the ascending and transverse mesocolon. The whole of the small gut was much distended. The intussusception was reducible with difficulty.

Case 2.—A female aged five months was admitted into the London Hospital on Dec. 26th, 1902, with the history that the child was in good health until 5 P.M. on the previous day—viz., the 25th; she then suddenly woke up crying out. The mother gave her a teaspoonful of syrup of rhubarb. Blood was noticed in the next motion and a good deal of blood passed during the night in four or five motions. The child began to vomit in the night; this had continued up to the time of admission. The child had always been breast-fed. On admission she was found to be a healthy and well nourished child not markedly collapsed, but the extremities were cold and there was general restlessness. On abdominal examination a well-defined sausage shaped tumour could be felt lying transversely across the abdomen and extending to the left iliac region. The apex of an intussusception could also be felt easily per rectum. The rest of the abdomen was flaccid and not distended. Operation was performed half an hour after admission. A median incision was made below the umbilicus and two fingers were inserted; an attempt made to reduce thus proving unsuccessful the tumour was brought up to the wound and reduced fairly easily, the last portion to be reduced being the caput cæci. The abdominal wound was sutured with silkworm gut. The time occupied in operation was 15 minutes. With regard to her progress restlessness was marked after operation. Two minims of nepenthe were given with very good results. The bowels acted three hours after operation; the first motion contained blood. The temperature rose to 104° F. on the evening of the operation day; this subsided to normal two days later. The after progress was uneventful. The sutures were removed on the tenth day and strapping was applied.

Case 3.—A male aged six months, was admitted into the London Hospital on Dec. 29th, 1902, with a history that two days previously at 6 P.M. he began to scream, and shortly after blood and slime were passed per rectum; the bowels had not acted since. Vomiting had been incessant. The child had always been breast-fed. On admission he was found to be a well developed child. Some amount of shock was present and whilst being examined vomiting occurred with apparently no effort. On examination general rigidity of the abdominal wall was found. No tumour was made out on palpation and nothing definite could be felt per rectum. The examining finger was, however, coated with bloody mucus. Operation was performed. Under anæsthesia a tumour was easily felt in the right iliac and hypochondriac regions, placed vertically. An oblique incision about two and a half inches in length was made in the right semilunar line. The intussusception was brought up to the wound and reduced. This was effected with some difficulty, the peritoneum of the ensheathing layer being torn for about one inch transversely. This was not sutured. The last two inches of the ileum were invaginated through the ileo-cæcal valve and so formed the apex of the intussusception. This had drawn the ileo-cæcal valve with it, constituting the is shown by Mr W O C Pakes's analysis of 304 consecutive cases in which the error was only 3 03 per cent. In doubtful cases a morphological examination of the blood should be made, and if, in addition to a slight or indefinite serum reaction, there are an absence of leucocytosis and a relative lymphocytosis the disease is, without much doubt, typhoid fever A negative serum reaction does not necessarily prove that the patient is not suffering from typhoid fever If the clinical evidence is sufficient to make the diagnosis certain a negative serum reaction should in many cases be looked upon as a warning of the possibility—in fact, I might say of the probability—of a relapse.

CASE 16.—Last year I had under my care a boy who was undoubtedly suffering from typhoid fever Repeated attempts at obtaining a positive serum reaction failed until the beginning of the tenth week of his illness, when a third relapse was commencing

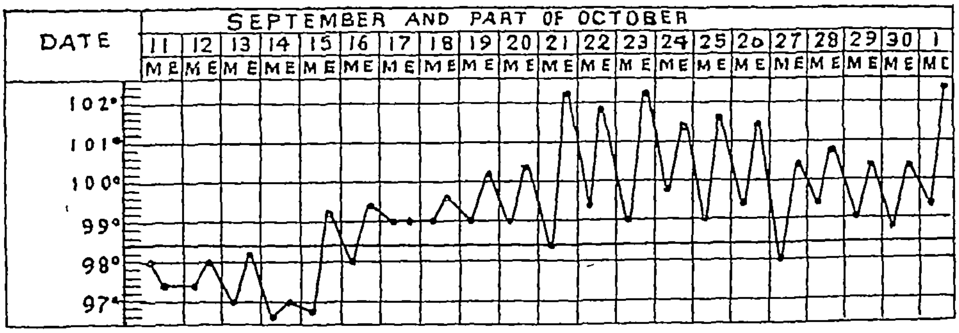

Chart of temperature in case of ambulatory typhoid fever with relapse. Positive serum reaction on Sept. 14th

CASE 17 —Lying in the bed opposite to the patient in the preceding case was another boy suffering from the same disease whose serum did not give a positive reaction until the middle of a second relapse.

The following case illustrates the value of the reaction in making a diagnosis of typhoid fever

CASE 18.—A male, aged 25 years, was admitted on Sept. 11th, 1901, for debility resulting from diarrhœa. He commenced to feel ill a month before admission and complained of headache, diarrhœa, pain in the abdomen, and sickness. The diarrhœa continued and he could not check it with medicine. He became weaker and lost weight, but did not have to keep to his bed. On admission his temperature was 98° F , his pulse was 72, and his respirations were 24 The abdomen was not distended and the spleen was just palpable. There were no spots. The stools were liquid and pale The possibility of ambulatory typhoid fever was considered and three days after admission his blood serum gave a positive reaction when diluted to 1 in 200, the temperature being 97° (*vide* Chart) A week after admission the temperature began to rise and he had a relapse The diagnosis of this case as one of typhoid fever was much helped by the positive serum reaction.

Malta fever may be diagnosed by means of a similar serum reaction if a culture of the bacillus Melitensis is mixed with the serum from a patient suffering with this disease.

IV *The bacteriological examination of the blood* —Great care must be exercised to prevent the possibility of the blood which is obtained for bacteriological examination being contaminated. The staphylococcus albus, if found, is due to contamination and is not the specific cause of the disease from which the patient is suffering The micro-organism which is most frequently obtained by cultivating the blood is the streptococcus pyogenes I have obtained it in a good many cases of infective endocarditis. If a patient is suffering from some valvular lesion, has an irregular temperature, is anæmic, and streptococci are obtained by cultivating the blood a diagnosis of infective endocarditis can be made and the indication for treatment is the injection of anti streptococcic serum A question which is often asked is—Is infective endocarditis invariably fatal? The following case bears on this point.

CASE 19 —A boy, aged 15 years, was admitted to hospital suffering from mitral disease. He had had several attacks of rheumatism. His temperature was varied and was running an irregular course, ranging between 98° and 101 5° F When he first came under my care he had been in the hospital for nearly two months and during the whole of this time his temperature had been raised and he had not had any manifestation of rheumatism or of tonsillitis. A bacteriological examination of the blood showed the presence of streptococci in pure culture A few days afterwards the temperature dropped to normal and remained normal. A subsequent bacteriological examination of the blood was negative. I considered that this boy was suffering from infective endocarditis, that the acute process had subsided, and the streptococci had died out

I have endeavoured to show in this paper what can be learnt by examination of the blood in certain diseases. It is only a sketch of the subject which is one of very great interest to me. I hope I have not given the impression that I believe blood examinations are infallible as an aid to diagnosis and prognosis. I fully indorse what Ewing writes, "The examination having been performed *its results are to be interpreted only in the light of the fullest possible clinical information.*"

NOTE ON THE RESULTS OF THE TREATMENT OF AN UNUSUAL SERIES OF CASES OF ACUTE INTUSSUSCEPTION

BY HUGH M RIGBY, M S LOND , F R C S ENG.,
ASSISTANT SURGEON TO THE LONDON HOSPITAL SURGEON TO THE POPLAR HOSPITAL FOR ACCIDENTS

DURING the nine days from Dec. 26th, 1902, to Jan. 3rd, 1903, no less than seven cases of acute intussusception were admitted into the surgical wards of the London Hospital. As I was fortunate enough to be the surgeon on duty during this period I had the opportunity of seeing and dealing with them all It seems worth while to record the notes and results of treatment of these seven cases, six of which were submitted to operation. The result—viz., five recoveries out of the six operated upon—is distinctly encouraging and should be a strong argument in favour of early resort to surgical interference in these too often fatal forms of intestinal obstruction Statistics of cases of acute intussusception with the results of their operative treatment have been dealt with by many writers. It seems to me that in no class of case can statistics be of less value than in this, the operative mortality must vary enormously from time to time, depending as it does on such slight alterations of the pathological changes found within the abdomen. The very fact of the invaginated portion of the gut being irreducible immediately causes the mortality to rise from, perhaps at the best, 50 to 90, or even 100 per cent. The age of the patient also has a marked influence on the prognosis, while the duration of the illness before its serious nature is recognised is another all important factor which has to be reckoned with. The notes of my cases show that of the six operated on only one was to a very small percentage, and (5) that the chief points in the after treatment are (*a*) early feeding and (*b*) the use of opium when necessary In conclusion, I have to thank Dr E F Fisher and Mr F G Bowen, house surgeons, for their valuable aid in the care and after treatment of these cases

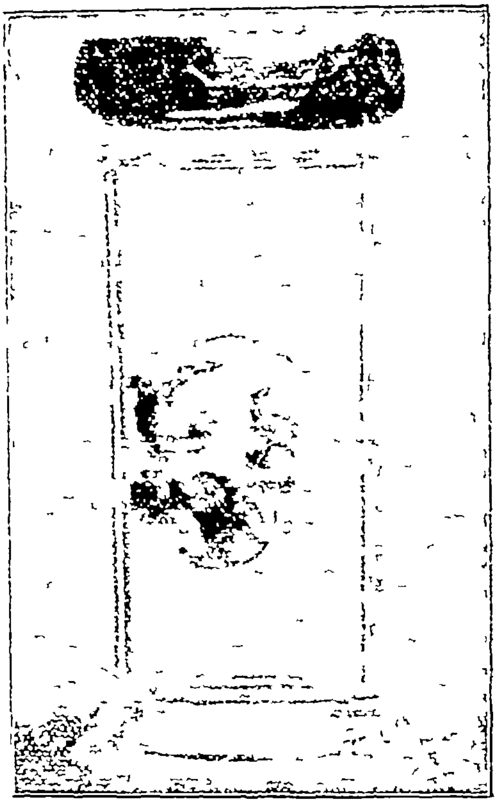
Wimpole-street W

A CASE OF EXTRA-UTERINE FŒTATION

By THOMAS H. MORSE, F R C S Eng

FEW conditions are more alarming than that which may occur to a young wife apparently in the best of health by the rupture of an extra uterine fœtation. We owe much to the courage and investigations of the late Mr Lawson Tait on this subject. He it was who first demonstrated to us the way to rescue these cases from imminent death by a timely operation. The following case occurred in Norfolk I hope in the near future to bring before our profession a series of 20 of these cases which have occurred in my practice, trusting that the details of them may be of service in illustrating important points in diagnosis and treatment for the future. I have entered fully into details as this case is typical of many others that I have operated upon, and I believe the condition to be more common than is generally supposed, early recognition being of the greatest importance.

The patient was a woman, aged 30 years, who was under the care of Dr A. R. Manby, Mr H. E. Rowell, and Mr Hogg, with whom I saw her She had been married two months and menstruation was missed for the first time three weeks before I saw her There had been no subjective signs of pregnancy She was feeling quite well until 3 A.M on Jan. 5th, 1903, when she was seized with violent abdominal pain followed by faintness and temporary blindness She was sick once and the abdomen was very tender to touch The pulse was 130 and the breathing was rapid and thoracic Pain was referred to the right inguinal region The symptoms of loss of blood increased until pallor and collapse were extreme and she appeared to be dying The diagnosis of ruptured tubal pregnancy was made by Mr Hogg and confirmed by Dr Manby and Mr Rowell the same evening Operation was advised but refused. In response to an urgent summons I saw her on Jan. 6th Before my arrival saline fluid had been injected into the rectum and the pulse had considerably improved in consequence. The patient at that time looked extremely ill and could not speak above a whisper Extreme pallor showed itself in the lips, gums, and tongue, and especially in the conjunctivæ The abdomen was distended and resonant all over the centre, but dull or nearly so in both flanks. The pulse was still feeble—130 per minute—though much improved by the saline injection. The temperature was 96° F The uterus seemed somewhat fixed and Douglas's pouch contained a resistant semi solid mass. The abdomen was not tender to touch anywhere—a sign which I have before noticed in these cases and a valuable one as a diagnostic distinction from perforation of the stomach or other hollow viscus Abdominal section was decided upon. Every precaution having been taken as to asepsis, Mr Hogg gave ether and Dr Manby and Mr. Rowell assisted As soon as the peritoneal cavity was opened a large quantity of dark blood escaped, the pelvis was completely full of clots. As the history given pointed to the right side as the place of origin of the trouble I at once drew up the ovary and tube of that side when a small tubal pregnancy not larger than a hazel nut was found close to the uterine end of the tube. Here let me remark that I have noticed that the nearer the gestation sac is to the uterine end of the tube the greater in amount has been the hæmorrhage in these cases The tube was ligatured with silk and the whole of it including the pregnancy, was removed, large handfuls of clots were then removed and the abdomen was washed out with sterile hot water The wound was closed completely with three rows of suture, catgut being used for the peritoneum and muscle and fishing gut for the skin. A large quantity of water was purposely left inside. The wound was dressed with cyanide gauze and collodion Shock was not severe and the pulse quickly improved in volume and remained at 120 per minute for the next 12 hours. Judging from the daily reports that I received from Dr Manby and my nurse I find that the convalescence was rapid and uneventful, the wound having united by primary union.



The illustration shows the Fallopian tube, the upper end being the normal fimbriated extremity and the expansion at the lower end being the gestation sac, it is the smallest I have ever seen which had given rise to so much hæmorrhage.

Norwich.

FURTHER INVESTIGATIONS REGARDING THE INFECTIVE NATURE AND ETIOLOGY OF PERNICIOUS ANÆMIA.

(25 CASES)

(SYN IDIOPATHIC ANÆMIA OF ADDISON")
ITS NON IDENTITY WITH THE 'PROGRESSIVE PERNICIOUS ANÆMIA" OF BIERMER

BY WILLIAM HUNTER, M D EDIN F R C P LOND,
PHYSICIAN TO THE LONDON FEVER HOSPITAL EXAMINER IN MEDICINE IN THE UNIVERSITY OF GLASGOW

(*Continued from p 253*)

THE evidence on the points already mentioned I shall now consider

VII —GENERAL ETIOLOGY OF 25 CASES.

General etiology —The facts in connexion with the general etiology in the 25 cases observed in the past three years may be summarised as follows —*Age* varied from 32 to 72 years The average age was 51 years, the majority of the cases being between the ages of 40 and 60 years *Sex* 19 cases were in men and six were in women. *Station in life* There were 17 private patients and eight hospital patients. *General health* in all the cases was good *Poverty* In no case did this play any part in the production of the disease, nor did *bad food* or *insufficient food* As one of the hospital patients put it, he had always been careful about what he ate and drank and had been in a position to gratify his wishes in those respects. *Pregnancy* or *puerperal troubles* In none of the six cases in form described by Lichtenstern as ileo colic iliaca. The abdominal wound was closed with silkworm gut The time occupied was altogether 10 minutes. Progress was uneventful. No stimulant or opium was required There was a slight rise of temperature—viz, 100° F on the day after operation. Feeding was commenced as soon as the effects of the anæsthetic had passed off. The sutures were removed on the tenth day

CASE 4 —A male, aged six months, was admitted into the London Hospital on Dec. 29th, 1902, with the history that the child was quite well until 7 30 P M on the 28th He then began to scream with pain, some brandy was given, and a good deal of blood was passed in the motions during the night and vomiting was frequent. The child had always been breast-fed. During the last week he had had diarrhœa. On admission he was found to be a well nourished child. He lay in an apathetic condition and the pulse was small and quick. On examination the abdomen was generally flaccid and a well marked sausage shaped mass could be easily felt in the left hypochondriac and iliac regions Per rectum the apex of an intussusception could be easily felt within one and a half inches from the anus Operation was performed. A median incision was made below the umbilicus The intussusception could not be reduced without exposing it through the wound There was some difficulty in reduction, especially the last two or three inches, the apex was formed by the caput cæci, the cæcum and appendix were much injected, œdematous and covered with thick lymph, this was gently sponged away The wound was sutured with silkworm gut The time occupied was altogether 15 minutes. After operation there was much collapse, the child was restless and his extremities were cold, $\frac{1}{150}$th of a grain of strychnine was given hypodermically and two minims of nepenthe. The bowels acted nine hours after operation, some blood being passed. On the day following operation the general condition had much improved The sutures were partly removed on the ninth day, no strapping was applied A few hours later the child was sick and on examining the abdomen the house surgeon, Mr F G Bowen, found that the wound had partly given way and that some small gut had prolapsed, he immediately under anæsthesia replaced the protruded portion and resutured the abdominal wound. The further progress of the case has been uneventful

CASE 5.—A female, aged eight months, was admitted into the London Hospital on Jan. 2nd, 1903, with the history that she had been vomiting on and off for the last seven days Two days before admission blood was passed in the motions and a good deal since that time, slime had also been passed She had always been breast-fed On admission at 11 A M the patient was found to be a small undersized child but well nourished She was evidently suffering from collapse, the lips were pale and the eyes were sunken. The pulse was thready On examination the abdomen was generally flaccid and a definite tumour could be felt in the left iliac region, no tumour could be made out per rectum Operation was performed at 1 P M A median incision was made below the umbilicus, the tumour was drawn up to the wound, the intussusception had extended into the rectum The apex proved to be the ileo-cæcal valve There were much swelling and œdema of the lower end of the ileum, cæcum, and appendix. During the necessary manipulations the child stopped breathing and artificial respiration was carried on for a few minutes. The abdominal wound was closed with silkworm gut The time occupied in operation was 15 minutes. The child was much collapsed immediately after the operation, ether was injected and half a pint of saline fluid was also introduced into the subcutaneous tissue. At 7 P M on the same day the child had vomited several times after the anæsthetic, she was very restless, the temperature had risen to 106° and the pulse was uncountable at the wrist. A rectal injection of saline solution (eight ounces) was given and a hypodermic injection of morphia (one twenty fourth of a grain) These had a very marked effect the child slept and next day was much improved On Jan. 8th the child had an attack of abdominal pain she vomited several times, and her temperature rose to 101° F Nothing was found on abdominal examination and further progress was uneventful The sutures were removed on the tenth day

CASE 6.—A male, aged five years, was admitted into the London Hospital on Jan 3rd 1903, with the history that the illness began on the 1st with abdominal pain There was no vomiting and nothing was noticed abnormal in the motions On the 2nd the boy had several attacks of colicky pain but he did not vomit He had been subject to attacks of colic and diarrhœa from time to time and he had attended the North Eastern Hospital for Children for tabes mesenterica. There was a family history of consumption. On the day before admission the bowels acted normally On admission he was found to be a well nourished boy, he appeared to be comfortable and free from pain The pulse was full and regular, 80 per minute On examination the abdomen was not distended, it moved freely on respiration, and there was no tenderness on palpation. An ill defined tumour could be felt placed transversely above the umbilicus, it felt nodular and somewhat moveable Nothing abnormal was felt per rectum A glycerine enema was given with the result that formed motions were passed quite free from blood or slime As the diagnosis was doubtful no immediate operation was thought necessary Next day, the 4th, at 12 noon, the child had vomited after milk four times during the night, the bowels had not acted. The temperature was 100° F The general condition was unchanged except that the abdominal tumour had quite disappeared. At 6 P M the child was again examined. No further vomiting had occurred, but there had been several slight attacks of colicky pain lasting only a few seconds at a time. On abdominal examination a well defined tumour could again be felt, it was situated transversely above the umbilicus, was slightly tender on palpation, and whilst being manipulated was found to enter into peristaltic action A diagnosis of recurring intussusception was made and operation was immediately decided upon. This was performed at 7 P M An incision three inches long was made in the right semilunar line, an intussusception was found formed by the last two inches of the ileum, this had passed through the ileo-cæcal valve and was there fixed. It was easily reduced, the wall of the gut was much thickened and congested. The abdominal wound was sutured with silkworm gut. The time occupied in all was 12 minutes. The after progress of this case was without incident. The sutures were removed on the tenth day

CASE 7 —A male, aged nine years, was admitted into the London Hospital on Jan. 3rd, 1903 with the history that the illness commenced with an acute attack of abdominal pain on Dec. 31st, 1902—i.e., three days before admission. There were continual retching and vomiting, the bowels were confined, and no blood or slime had been passed per rectum. There had been no previous history of abdominal trouble. On admission he was found to be a well nourished boy, evidently suffering from severe shock, the extremities were cold, the lips were blue, and the face was blanched The pulse was 160 per minute, thready and collapsable. On examination the abdominal wall was not rigid, but the whole abdomen was distended No definite tumour could be made out on palpation, and a rectal examination was negative—no blood was seen on the examining finger Stimulants were given and hot bottles were applied, and as the general condition improved shortly after admission to hospital an operation was decided upon The abdomen was opened in the mid line and a large coil of deeply injected gut was drawn into the wound, it proved to be small gut forming the insheathing layer of an intussusception, the mesentery of which was twisted on its axis The intussusception was partially withdrawn, there were no adhesions, the invaginated gut was found to be gangrenous, and an immediate resection was decided upon This was done as quickly as possible, about three feet in all were excised, including the intussusceptum and part of the intussuscipiens The cut ends of the gut were united by a Murphy's button. The abdominal wound was closed with silkworm gut There was profound shock after the operation. Saline fluid was injected and strychnine, caffeine, and brandy were given, but without any appreciable result, and death occurred six hours later. At the post-mortem examination it was found, as abovementioned, that the intussusception had been a retrograde one The contracted part of the gut continuous with the intussusceptum was found in a condition of commencing gangrene where the button had been inserted. There was early general peritonitis present.

To summarise briefly, the chief conclusions to be drawn from my short series are (1) that in these cases immediate laparotomy should be insisted upon without delay, (2) that no valuable time should be lost in attempting inflation of air or injection of fluids per rectum, (3) that the keynote of operative success is rapidity, (4) that in favourable conditions, as in hospitals and with skilled assistants, the mortality of reducible intussusceptions should be diminished other control analyses made in other conditions of profound anæmia is exceedingly striking.[2] In pernicious anæmia the average percentage of iron in the liver and kidney combined was 360 milligrammes, whereas in health it was 84, in profound sepsis 49, in cancer of the stomach 83 and in ulcerative phthisis 100 milligrammes. 1. It will be noted that I have always included the kidney among the organs analysed. This is a point to which I have attached more and more importance during the past 12 years for reasons which the present series of analyses bring out. It will be seen that the excess of iron present is not always equally distributed between the liver and kidney, in some cases—e.g., Cases 3 and 6—the percentage in the kidney being very large (to insure absence of any error I had the analyses in these cases repeated). If in Case 6 the analysis of the kidney had not been made the moderate percentage in the liver would not have accurately represented the amount of blood destruction that had occurred. The varying percentage in the kidney in different cases is notable. It depends, as originally explained in 1888, on the overflow of hæmoglobin from the portal circulation. "If the destruction is slight the products of it present within the portal circulation are completely disposed of by the liver before reaching the general circulation. If it is excessive at any one time the evidences of hæmolysis extend to the general circulation. Hæmoglobin in the form described passes into the general circulation and is excreted through the cells of the convoluted tubules of the kidney. The most likely cases, therefore, in which to find pigment in the kidneys will be those in which the progress of disease has been marked by specially severe exacerbations in which, therefore, the destruction has been very great" (1888). In Case 6 a notable exacerbation of this kind had occurred during the patient's last relapse, the blood corpuscles falling in the course of three or four weeks from 83 to 32 per cent. and the hæmoglobin from 82 to 35 per cent. 2. The analyses bring out also in a striking way the second point which was drawn attention to in 1888 as one of the marked features of the hæmolysis in this disease—the peculiar distribution of pigment between the liver and spleen. In health and in most diseases the spleen usually contains a higher percentage of iron than the liver (as these analyses show, than the liver and kidney combined) sometimes from six to eight times higher. In pernicious anæmia, on the other hand, as will be seen, in every case without exception this relation was reversed. The percentage in the liver alone exceeded that of the spleen, sometimes as much as five fold (Case 1). 3. I draw particular attention to the analyses (9, 10, 11) in cases of profound sepsis. They prove conclusively that sepsis alone, however severe, cannot cause the pigment changes characteristic of pernicious anæmia. Case 10 is a typical example of what I have termed "septic anæmia," the form of anæmia oftenest mistaken for pernicious anæmia (Addison's anæmia). It was sent to me as such a case and it resembled this in the general features and appearances in the degree and character of its blood changes, and in the presence of marked gastro-intestinal symptoms and extreme oral sepsis. But the urine showed no hæmolytic changes and there was no history of the glossitis which I regard as characteristic of pernicious anæmia, and I therefore declared it to be non-pernicious and probably of the type of "septic anæmia." A trace of albumin subsequently appeared in the urine, and the patient died from uræmia two months later. At the necropsy I found a large perinephric abscess in the left loin connected with a calculous pyo-nephrosis of which there were no symptoms during life. The pigment changes strikingly contrast with those of pernicious anæmia. 4. Of special interest, also, are the analyses in gastric cancer (12 and 13)—in view of the very prevalent view that gastric cancer may simulate pernicious anæmia and be a cause of that anæmia. Case 13 was a typical case of this kind, presenting the lemon colour of pernicious anæmia. The low percentage of iron in all the organs is very striking. Case 12 was a case of cancer involving the whole body of the stomach. The high percentage of iron in the spleen in this case as also in the case of ulcerative phthisis is noteworthy. It is the condition typically found in long-standing wasting disease depending on inanition. It denotes for reasons I have elsewhere explained, a lessened, rather than an increased, hæmolysis. If pernicious anæmia could be produced by inanition the result of gastric atrophy, achylia gastrica, &c., as so many maintain, the distribution of blood pigment between the spleen and the liver would be that illustrated in Analyses 12 and 14, rather than that one just drawn attention to in Analyses 1–7. 5. The importance attached since 1888 to pigment changes by all English, American, and Canadian observers is in striking contrast to the neglect of this subject which is the most remarkable feature of German work during the past 25 years. In the latest German monograph on the disease (1900) Ehrlich and Lazarus dismiss the subject in three paragraphs occupying half a page. In my own monograph (1901) 250 pages out of a total of 450 are devoted to the studies connected with this subject. During the same period I know of no new analyses in German literature, whereas in English literature there are at least 54—viz., 19 in pernicious anæmia and 35 in other conditions.

Table of Analyses. Percentage of Iron in Organs in 14 Cases.

No. of case	Condition	Liver	Kidney	Spleen
1	Pernicious anæmia	0·360	0·033	0·069

X.—INFECTIVE ETIOLOGY OF THE DISEASE.

If I have been able to throw any light on the nature and etiology of the severe conditions of anæmia comprised within Addison's and Biermer's widely different conceptions it is largely due to two circumstances. 1. It was my good fortune to approach the subject (1885), not from the surface where my attention would probably have been engrossed by the conflicting views—historical, clinical, and etiological—connected with the disease, but from the ground (pathological) underlying the whole group of these severe anæmias. 2. While working there I came almost accidentally as it were, upon a great bed rock of hæmolysis underlying Addison's anæmia (1885) and in endeavouring to expose its size and relations (1886–87) I no less suddenly found the whole superstructure built upon Biermer's different foundation women did pregnancy or puerperal troubles play any part. *Loss of blood* In no case was there any previous loss of blood and in the few cases—the very small minority—in which epistaxis occurred this was only slight in amount and not very frequent in occurrence, it occurred only after the disease was already well developed and was not a factor in its original production *Malignant disease* In none of the 25 cases was there reasonable ground for suspecting malignant disease (two cases in which this question arose I have purposely excluded) and in none of the seven cases examined post mortem was any malignant disease found *Gastric or intestinal disturbance* A history of antecedent gastric or intestinal disturbance, as I shall presently show, was found in every case. In no case were these of sufficient character or intensity to account for the supervention of such an intense degree of anæmia. The various disturbances connected with this tract have an important significance, which I have brought out, not as causes of the disease but as symptoms of the gastric and intestinal infective lesions presently to be described associated with the disease.

---

[2] Analyses specially made by Mr. Percy Richards, F.C.S., of Charing Cross Hospital. (For method see THE LANCET of Nov. 24th, 1900, p. 1495.)

Anatomical lesions —In all the cases observed during life, 25 in number, and in the cases, seven in number, in which post-mortem examinations were obtained, I found certain infective *lesions* in the *mouth*, *tongue*, *stomach*, or *intestine* —either singly or associated with each other These were of two classes (1) a special form of glossitis (in every case), (2) septic lesions—viz, (*a*) a preceding or existing "oral sepsis" (24 cases), (*b*) "septic gastritis," the condition I described (1900) as a common result of long continued oral sepsis, causing finally gastric atrophy (more or less in every case and most intense in three cases), and (*c*) "septic enteritis"—e g, a croupous enteritis, patches of congestion and catarrh, follicular enlargement, and patchy colitis (three cases) With regard to these the point to be emphasised now in view of the significance I shall subsequently attach to them is in no case were these lesions either in anatomical character or severity sufficient of themselves to *originate* the intense anæmia by any interference with nutrition they may have been capable of producing

Chronic discharges and suppurations —In no case were there any discharges or suppurations sufficient of themselves to originate the anæmia

Summary —In all the 25 cases the anæmia might well have been described in Addison's own words—viz, as 'occurring without any recognisable cause whatever, cases where there has been no previous loss of blood, no exhausting diarrhœa no chlorosis, no purpura no renal, splenic, miasmatic, glandular, strumous, or malignant disease and without any organic lesion that could properly or reasonably be assigned as an adequate cause of such serious consequences" (1856) On the other hand, in not one of the cases could Biermer's description of the etiology of "progressive pernicious anæmia," which has so largely influenced the views of most subsequent observers, be applied. "A spontaneous origin *without clear etiology* is the rule" In all the foregoing cases an apparently spontaneous origin was, on the contrary the rule *without exception*

Conclusion —The first clear conclusion in regard to the etiology of these 25 cases is this that even *on clinical grounds* the disease could not reasonably be ascribed to the ordinary causes of anæmia. since (1) it originated without the presence of these, and (2) each and all of these are often present in severest degree without causing the anæmia In that respect Addison's original etiological foundation has been proved, so to speak, even to the naked eye—i e, clinically—as far as my own work is concerned, to have been much more solidly laid than that of Biermer *Some other factor* was required to account for the disease in all these cases.

VIII.—Weak Foundations of Biermer's Etiology

Still weaker is Biermer's etiology pathologically To a degree which they themselves have never recognised or acknowledged, the whole fabric of Biermer's anæmia as built up by its workers has from the very first largely rested on Addison's foundation—that is to say, whenever its so-called causes have one and all been absent, the anæmia has been summarily disposed of by being termed the Addisonian variety—"primary, cryptogenetic'—and no further attempt has been made to throw light on its nature or mode of origin Moreover, even in the large group of "causes" which they consider responsible for the anæmia—e.g, worms, gastric disturbance, intestinal disturbance, hæmorrhages, &c.—all the chief exponents of "progressive pernicious anæmia" have to admit that these causes are not themselves sufficient but that 'something over and above" is required.

1 "A gross *disproportion between cause and effect*," "a kind of *predisposition*," are essential features (Eichhorst, 1891, Lazarus, 1900, Grawitz, 1901, Schaumann, 1900)

2. '*Something over and above* which transforms the worm from a comparatively harmless inhabitant of the intestine to an important disease-producer under certain conditions not yet fully ascertained," such is the admission that has to be made by Lazarus (Ehrlich and Lazarus[1]) with regard to the anæmia caused by the bothriocephalus, which he just immediately before declared to be "progressive pernicious anæmia with a known (*sic*) etiology fully (*sic*) explained in its etiology if not also in its pathogenesis."

3. "We cannot explain these blood diseases without assuming the existence of *an individual predisposition* many points still dark in this difficult subject, notably *the extraordinary persistence and progression of the disease after to all appearance the cause is removed*" Such is the admission of Professor Grawitz, one of the strongest and most recent (1901) upholders of the theory of the gastro-intestinal origin of the disease from auto-intoxication, its cause being "a vicious circle" of blood changes, gastro intestinal lesions, altered digestion and absorption, and auto-intoxication, the auto-intoxication causing the blood changes, these causing the atrophy of the glands, this atrophy producing altered digestion and absorption (which in turn increases the anæmia), and this latter causing the auto-intoxication And yet, curiously enough the disease persists and progresses after all these "causes" are removed A similar *predisposition* is admitted by Dr Schaumann to be necessary for the occurrence of the severe anæmia (which more than any other observer he has studied and thrown light upon) associated with bothriocehapalus anæmia, "since there are a great number of men whose blood is not in the slightest degree affected by the worm, *although the worms of these men contain*, as shown by Dr Schaumann and Dr Tallqvist, *the same toxic bodies as other worms* (1900)"

4 "*The causes of the initial anæmia are still imperfectly known*, and cases sometimes occur in *people apparently healthy and living under good conditions* In some cases after death hæmorrhages have been so few that I have doubted very seriously whether they could ever have been very numerous so very few that this might lead us to adopt Hunter's view that in some cases at least a blood-destroying body may be the cause of the condition." Such is the admission of Professor Stockman, the most recent and chief upholder of the view that the disease is due to the ordinary causes of anæmia aggravated by internal hæmorrhages (1895)

Put together all these admissions and qualifications form an "underpin" of remarkable size and strength for an erection whose foundation, declared to be a solid one, is "that a spontaneous origin *without clear etiology* is the exception." (See Scheme.)

Conclusion.—General etiology cannot account for this anæmia It has a special etiology underlying it.

IX.—Special Etiology

There are two classes of lesions which I consider of importance in this relation—(1) a Hæmolysis of special degree and character, well shown by the analyses in the present series of seven cases, and (2) a Glossitis, *observed in every case* having the peculiar relation to the onset of the anæmia and clinical characters suggestive of its being of an infective nature, described by me in 1900 Histological examination in seven cases shows that it has even more striking pathological features, and in all the three cases bacteriologically examined these are associated with, and presumably dependent upon, a deep-seated pure streptococcal infection of the substance of the tongue

Hæmolytic Nature of the Disease.

Analyses of the liver, spleen, and kidney in seven cases show (1) the large excess of iron, and (2) the peculiar distribution between the liver and the spleen—the reversal of that usually obtaining—to which importance is in my judgment to be attached (1888) The contrast between the results obtained in pernicious anæmia and those obtained in seven

---

[1] Die Anaemie, Part 2, 1900

In these circumstances some new nomenclature appears sirable. So long as I was not myself clear as to the nature the large group of severe anæmias which simulated ddison's anæmia and yet, as I was satisfied, were essenally different, it seemed premature to give any new name to e disease. Now that in my own mind (as the result alike clinical and pathological experience) this great group has een definitely separated off as in a large measure of septic haracter and may be entitled "septic anæmia," I feel free suggest another name for Addison's form. It is really a ery remarkable *specific infective disease*, characterised by tense *hæmolysis* as its most prominent (although by no eans its only) pathological feature and consequently *næmic* as its most striking (but by no means its only) linical manifestation, and this onset of hæmolysis is ssociated with the onset of a peculiar *plurality* of *infective* ature. The title which would best describe its character ould thus be "specific infective hæmolytic anæmia," or nore shortly "*infective hæmolytic anæmia*" (Addison's næmia), the *specific* nature of the infection responsible for he hæmolysis being always kept in mind, just as the *pecific* nature of the infection is always kept in mind n the title "enteric fever." There are other anæmias complicated by hæmolysis just as there are other fevers complicated by enteric disturbance, but there is no anæmia in which hæmolysis plays such a remarkably preponderating part. There are also other anæmias in which infection plays a part—notably the large group I have designated "septic anæmia"—but in this group hæmolysis although in certain cases it may be marked is *not* the special feature that it is in Addison's anæmia, as the above analyses strikingly show

Harley-street W

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON A CASE OF NECROTIC SOFTENING OF THE BRAIN PROBABLY DUE TO INJURY AND ASSOCIATED WITH CARIES OF THE SPINE.

BY H. K. ABBOTT, M.D. DUB.
DEPUTY SUPERINTENDENT OF THE COUNTY ASYLUM, FAREHAM, HANTS.

THE patient had served in the Royal Navy and had been a smart active man until he had a fall from a height of 10 or 12 feet. Soon after this he developed epilepsy and was invalided out of the service I saw him first five years afterwards He was then thin and poorly nourished and had marked exophthalmos of both eyes the lids never being quite closed, the right pupil was larger than the left and both reacted sluggishly to light. The knee-jerk was normal. His muscles (especially those of the hands) acted in a jerky spasmodic way and he could not walk owing to lack of power of coördination He quite misjudged the distance of any object that he tried to touch and he appeared to be quite deaf but could, though with difficulty read written questions and nod or shake his head in reply He could also write, though very slowly and with great difficulty, the writing was sprawling and almost illegible but when it could be deciphered the words were correctly spelt and rational After some months however, the process of writing became more difficult and the spelling was generally incorrect. He had severe epileptic fits at intervals of from one to three or four months Except that he gained flesh to some extent there was little change in his condition for about five years He was then observed to have a fluctuating swelling in the right lumbar region just above the iliac crest and close to the spine. Some pus was aspirated from this and afterwards there was no further evidence of any disease in that region. He always from the first complained of pain in the head (not localised) and in the legs, but never of any pain elsewhere and he never suffered from diarrhœa Towards the end of his life he did not take food well and lost flesh though not to a great extent, and he had epileptic fits more frequently He died about 15 years after the original injury

At the necropsy extensive tuberculous peritonitis was found. There was also a large post-peritoneal abscess with thick walls and divided into three compartments which communicated with each other by small openings. This involved most of the left psoas muscle but did not extend downwards beyond the pelvis, and it evidently originated from the bodies of the third and fourth lumbar vertebræ, which were carious to a considerable extent. The laminæ, &c., were sound There was nothing abnormal in the other abdominal or the thoracic viscera. The occipital bone was thickened for some distance from the junction with the left parietal bone which was also thickened in the adjoining part, the extra thickness being in the inner table which was about double that of the corresponding part on the right side. There was no indication of fracture. The tentorium on the left side was very thick and partly calcified. The pia arachnoid was slightly thickened and markedly congested, the grey matter generally was wasted, and the left lateral ventricle was much dilated at the expense of the temporo-sphenoidal lobe chiefly The whole of the occipital lobe on that side and what remained of the lower part of the temporo-sphenoidal presented the appearance of yellow softening The cerebellum was small and very soft, almost pulpy, and of a yellowish colour and no structure was visible to the naked eye beyond the peduncles It is, I think, highly probable that the brain lesions at any rate, and possibly the disease of the spine, had their origin in the injury sustained at least 15 years before death.

Fareham, Hants

A CASE OF SCURVY OCCURRING IN AN INFANT

BY DAVID YOUNG M.B EDIN,
RESIDENT MEDICAL OFFICER, FLEMING MEMORIAL HOSPITAL FOR DISEASES OF SICK CHILDREN NEWCASTLE-ON-TYNE.

A CHILD four months old, was brought to the *Hospital for* Sick Children, Moor Edge, Newcastle-upon-Tyne, with a history of persistent vomiting and diarrhœa of two weeks duration, which had been unsuccessfully treated at home For some time before admission the child had been fed partly on fresh cow's milk and partly on condensed milk. The infant was very collapsed on admission and had *to be freely stimulated.* After some time the stomach and colon were thoroughly washed out. The diet then ordered was bovinine and barley water, with the addition of a little white of egg The treatment was so far successful that there was no return of the vomiting, the diarrhœa soon subsided and during the week

---

which appeared in THE LANCET (Sept 28th, 1901, p 851) The writer at the very outset notes as the most remarkable feature of the work—one which he apparently regards as detracting in some way from its value—the contrast between the uncertainty with which I speak of the etiology of the disease and the certainty of my conclusions regarding its pathology And then, quite misled by "an impression" that I should have liked to ascribe the disease to bad teeth," he adds, "All this serves to *render* (*sic*) the etiology of the disease very involved." As the remainder of the review clearly shows the *anæmia* he has in view is the same one I have in view—viz. Addison's anæmia—but what *etiology* has he in mind—that of Addison or that of Biermer? The most notable feature of Addison's anæmia notoriously was and has always been the mystery of its cause and, in reality the difficulty all have had in getting at its cause might justly be regarded as the greatest possible tribute to Addison's clinical acumen, since it was the absence of "any discoverable cause" which first led him to describe the disease as a "very remarkable" one. Moreover the caution with which I speak of the class of facts which I have brought into etiological relation with the disease might well be regarded as rather a subject for approval, contrasting as it does with the absolute assurance—in my judgment quite groundless—with which from Biermer's time, 1871 down to the present moment the majority of observers speak of the disease as due to *many causes*. On the one side therefore is Addison asserting that the disease is "without discoverable cause" on the other Biermer and many chief workers at the disease asserting that "a clear etiology" is the rule and it is this chaos that I am charged with "rendering" very involved. As a matter of fact in his interest in following my very difficult and halting endeavours to expose the foundations of what was termed by Addison "without discoverable cause" the reviewer has inadvertently overlooked the most important fact—namely that my work involves the most emphatic conclusion regarding etiology reached by any observer since Addison first defined the disease as "without discoverable cause." The conclusion namely is that the whole fabric of etiology built up and around Addison's anæmia by later workers has no real foundation and, so far as I am concerned has since 1883 been completely demolished and cleared away leaving Addison's foundation once more standing out clear and well defined and largely exposing (1) its hæmolytic nature (2) oral, gastro-intestinal site and (3) the infective factors underlying it If the result of this is to render the etiology more involved, what can be said of the alternative view—viz. that the disease can be caused at once by all sorts of causes and without discoverable cause tumbling about my ears For instead of a bed rock of hæmolysis, such as I found *in all cases* of Addison's anæmia, I found, underlying Biermer's anæmia, a mass of rubble of various kinds of which hæmolysis was quite the *least* prominent constituent. 3. In consequence of these observations I was able to recognise and to point out very early (1888) the existence of the great 'underpin" (C) which the chief builders upon Biermer's foundation are recognising only now (1891, 1895, 1900, 1901)

"With regard to all these so called causes—gastritis worms, cancer (*et hoc genus omne*)—it is necessary to assume that there have been superadded *certain other factors* essential to pernicious anæmia *on which its characteristic features depend* In the case of bothriocephalus latus *some pathological factor other than the presence of worms must be at work* to explain, on the one hand, the frequent presence of worms without anæmia, on the other hand, the occurrence even in Finland of cases of pernicious anæmia—specially intractable cases too—without any worms. For these reasons I am compelled to conclude that, as with malignant disease so with intestinal worms, *their presence alone* cannot be held as sufficiently accounting for the pernicious anæmia *occasionally* associated with them" So I wrote in 1888[3] as the outcome of the "Investigation into its Pathology" then published, and from that time to the present the object I have steadfastly kept in view has been to seek for an explanation of this anæmia in causes other than those built upon Biermer's foundation For further experience only served to confirm the conclusions already come to "In my own mind no fact stands out more clearly in connexion with the etiology of the disease than that none of the above causes (Biermer causes) can of themselves produce Addison's anæmia with its characteristic hæmolytic changes" (1900) On the contrary, my endeavour has been to expose more and more the bed rock of hæmolysis underlying Addison's foundation (1890–1900)

The result has been not only to expose this but to reveal two sets of infective factors, (1) a *specific* (hæmolytic) *infection* whose site and lesions (the tongue, stomach and intestine), approximate time of contraction, and probable source I have, I think, been able to lay partly bare, and (2) while doing this to lay completely bare a great stratum of *septic infection* traversing the foundations of Addison's anæmia forming to a large extent the foundation of those forms of severe anæmia which clinically most resemble pernicious anæmia.

XI —THE FEATURES OF "SEPTIC ANÆMIA" AND "ADDISON'S ANÆMIA" RESPECTIVELY

It is, I find, this septic infection which gives to the heterogeneous group of anæmias comprised within Biermer's definition "progressive pernicious anæmia" the resemblances which have led them to be mistaken for Addison's anæmia. In them the "septic factor" is so predominant that I have for some time past distinguished them in my own mind by the title of "Septic Anæmia." The features of severe forms of this anæmia are (1) most of the blood changes found in Addison's anæmia, including the existence of poikilocytes normoblasts, and megaloblasts, to which so much *distinctive* importance has (erroneously, in my experience) been attached by Ehrlich and most observers, (2) hæmorrhages, (3) dirty yellow anæmic complexion, (4) very frequently the existence of oral, gastric, and intestinal sepsis and symptoms, (5) fever, (6) severe and often fatal course the disease takes, (7) nervous effects and symptoms in many cases, and (8) favourable prognosis if cause be removed in time

In Addison's anæmia, on the other hand, the septic factor is, according to my observations a most important antecedent and concomitant, *but not the only factor* It precedes the disease, creating conditions of mucosa in mouth stomach, and intestines which permit *the contraction* of the *specific* (hæmolytic) *infection* underlying the real characteristic features of the disease. Its features include those above mentioned in connexion with "septic anæmia," generally more marked and of greater severity than in septic anæmia. They include, however, certain features which mark it off from simple septic anæmia. 1. Most important pathologically, an *intense hæmolysis*, accompanied by pigment changes in the liver, kidney, and spleen—these changes being, according to above observations and analyses made during the last two years, no less characteristically absent in "septic anæmia," even the severest forms. 2 The occurrence of a *glossitis* possessing *peculiar clinical features*, as I before described (1900), and even more *striking pathological characters*, as I have since found, and associated with a deep-seated *infection* of the tongue itself, as I now have ascertained bacteriologically (in three cases). 3 The contraction of this infective glossitis coincides approximately with the onset of the severe anæmia and its accompanying hæmolysis, so that in many cases with a clear history the patient can date the onset of his disease from a particular month when this glossitis was first noted 4 The source of this hæmolytic and glossitic affection which thus, comparatively speaking, *suddenly* comes on is connected —when the history can be clearly obtained—in all cases with an *exposure to drain poisons* (five cases) 5 The hæmolytic infection once taken root in the mucosa and substance of the tongue, in the mucosa of the stomach, and in some cases in the mucosa of the intestinal tract is extraordinarily persistent, healing up in one part for a time, then spreading to another—these variations in activity as they can be seen during life in the tongue being attended by an aggravation of all the features of the disease—viz., increased anæmia, increased hæmolytic changes (in the urine), increase of glossitic, gastric, or intestinal symptoms, and increase of toxic (febrile and nervous) disturbances

XII —NOMENCLATURE.

To mark off this "remarkable disease," as Addison truly called it, from the mixed group of "symptomatic conditions due to many causes" described and spoken of as "progressive pernicious anæmia," and by many as "pernicious anæmia," has thus in my judgment become an even greater necessity than it was when Addison first described it "Addison's anæmia" would fitly describe it if Addison's name were not already associated with another disease and as I have already had occasion to appreciate, confusion might arise by using the term "Addison's anæmia" only The term 'idiopathic" has been given a generic significance and cannot now be restricted to one form of anæmia, even if it were any more satisfactory than such terms as "primary," "essential," "protopathic," "cryptogenetic," which it is not I have myself always employed the title "pernicious anæmia" as referring to the rare form of anæmia had in view by Addison, occurring "without discoverable cause", and it has become quite a task each time one writes to explain that it is to this form, and not to the "progressive pernicious anæmia" of Biermer, "due to many causes," that one refers But many writers—I fear the majority—use the title "pernicious anæmia" in a generic sense, as including all forms of severe anæmia—"pernicious anæmias" as Grawitz calls them—and the result so far as I am concerned is endless confusion, as I have recently had occasion to note.

Views and conclusions are ascribed to me absolutely opposed to the whole tenour and character of my work from first to last, which notoriously have been to emphasise in every direction from which I have approached the subject the *special nature of this anæmia* If my work proves anything at all it is that none of the ordinary causes of anæmia —whether they be the older ones, gastritis, gastric atrophy, worms, hæmorrhages, altered digestion altered absorption, and auto-intoxication—or the new set of conditions which I have recently brought into prominence—bad teeth, pyorrhœa alveolaris, "septic gastritis," or the whole group of septic mouth conditions which I have comprehensively designated "oral sepsis"—can of themselves produce Addison's anæmia with its characteristic hæmolytic changes. I thought to make this quite clear by such statements as that "none of these conditions (e.g., mouth conditions), however severe, can be held to be the direct cause of so rare a disease Even in the cases in which they are most intense[4] they cannot be regarded as the causes of the disease" and thus felt quite free to discuss the important rôle which (always subordinate to the above conclusion) they one and all might "nevertheless" play. All views and statements such as that I ascribe 'pernicious anæmia" to "bad teeth," "pyorrhœa alveolaris,' or "foul mouths"—or that I "should like to ascribe pernicious anæmia to such causes"—are not only quite wrong, more than any other conclusion they would stultify my whole work on this disease, which, as stated, has been to point to its very special nature[5] of fat present.—Dr GLYNN said that he had seen scurvy arise in people who had been put on a strict diet for flatulent dyspepsia. He thought that some brands of Swiss milk were quite suitable for infant feeding up to seven months.—Dr F B O'FLAHERTY had found it difficult to get a good mixture with added cream; butter or cod liver oil was better The cream might however, be given separately.—Dr RAW, Dr BUCHANAN Dr GRÜNBAUM, Mr. W B. BENNETT, and Dr LLEWELLYN A. MORGAN spoke, and Dr DAVIDSON, in reply, said that although the cases were still rare, yet the disease was on the increase, apparently from the greater use of preserved milks. In his experience there was no preserved milk that could equal fresh cow s milk suitably modified.

[3] THE LANCET, Sept. 22nd 1888 p. 555

[4] Op cit. 204 1900

[5] Nothing better illustrates the confusion caused by the terminology of this disease than some of the criticisms which have been made in certain reviews of my recent work. One of the most careful of these is that

The Suture of Divided Nerves.—Ventilation of Bedrooms.—Stone in the Female Bladder

A MEETING was also held on Jan. 29th, Mr RUSHTON PARKER, the President, being in the chair

Dr NATHAN RAW showed a case in which he had successfully United the Severed Median and Ulnar Nerves several months after division The point to which he wished to draw special attention was the return of sensation within 24 hours of the operation.—Mr DAMER HARRISSON had performed many experimental operations with Professor Francis Gotch and had had several successful cases. He had found experimentally that impulses never passed through the nerve before the tenth day Sensation returned first, then the trophic lesion passed away motor power followed and finally electrical reactions were obtained.—Sir WILLIAM M. BANKS recalled cases, which he had shown to the society in which he had employed the sciatic nerve of the dog and the sheep to repair the injured median and ulnar nerves in man. At the great St Helen s glassworks division of the latter nerve was of no infrequent occurrence, and in former days, when no attempt at primary suture was made, it was very curious to observe what an amount of sensation and motion gradually returned after two or three years This was explicable on the "loop-line" theory, but in Dr Raw's case the immediate return showed that the nerve current had at once found its way back through the old route Viewing a nerve in the light of an electric telegraph cable, with each thread of the nerve corresponding to each wire of the cable, they knew that when a broken cable was repaired it was necessary to unite the broken ends of the identical wires whereas when a nerve was joined either immediately or through the intervention of some piece of indifferent tissue it was not possible to join the identical nerve fibres and yet messages were transmitted Might not the principle of Marconi s wireless telegraphy explain this? Let them suppose the divided ends of the fibres of a nerve to be attuned to each other like Marconi s masts, then any impulses sent along the proximal end from the electrical battery the brain, could be conceived as travelling through a suitable medium to reach the distal end without the necessity of intervening fibres (wires) at all.—Mr G G HAMILTON had operated on a number of cases by simply suturing the divided ends and the results had been quite satisfactory Two cases were mentioned where division of the nerves was overlooked by chemists. In seven cases a few hours after the divided nerve was sutured sensation returned for about 24 hours, and then completely disappeared.—Dr A. G GULLAN asked as to the appearance of the distal portions of the nerves. After 14 weeks' separation he would have expected complete degeneration. In this case the immediate return of sensation could not be explained. He also thought that a considerable amount of the improved muscular power and movement was dependent on the long flexors, the nerve-supply of which came off about the seat of section of the nerves and the tendons of which Dr. Raw united at the operation.—Mr KEITH W MONSARRAT had had recently a similar case in which sensation was re-established 22 hours after operation. He thought that this rapid restoration showed that even in the absence of the integrity of axis cylinders the nerve as a whole was capable of conducting sensory impulses, and that the analysis of these impulses took place entirely in the cerebrum.—Dr. W ALEXANDER and the PRESIDENT also spoke and Dr. RAW replied.

Dr W MACFIE CAMPBELL read a note upon Bedroom Ventilation. After dealing with the changes in respired air and the rate of change necessary to maintain purity in rooms of varying capacity he said that a fire in the room was useless unless it was kept up The Hinckes Bird system and Tobin s tubes were unsatisfactory in his opinion. Dr Campbell found that the only really satisfactory plan was to have the bedroom window widely open He found sleep to be more refreshing and consequently fewer hours in bed were necessary and getting up was a pleasure. He was, moreover, never cold at night, and was freer from catarrh.—Dr F H. BARENDT agreed thoroughly with Dr Campbell s remarks. He hoped that it would become a tenet of personal hygiene that the air of the bedroom should be as pure in the morning as at night.—Dr W PERMEWAN the PRESIDENT and others spoke and Dr CAMPBELL replied

Mr G P NEWBOLT read notes of two cases of Stone occurring in the Female Bladder, one of which was removed by litholapaxy and the other by suprapubic cystotomy He dealt with the methods of removing stone from that organ and emphasised the fact that vaginal lithotomy might be followed by fistula and should only be practised on certain rare occasions.—Mr W THELWALL THOMAS, although particularly partial to suprapubic lithotomy, thought that such an operation in adipose females with ammoniacal urine was liable to lead to septic cellulitis He preferred vaginal lithotomy, if lithotrity was impossible.—Dr H. BRIGGS thought vaginal lithotomy had many advantages over the suprapubic route in adult females abundant evidence now existed in support of this view.—Dr E. T DAVIES, Dr T BUSHBY and Dr W ALEXANDER spoke, and Mr NEWBOLT replied.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 28th, Dr J Nigel Stark, the President, being in the chair.—Specimens were shown by Dr E. A. Gibson, Dr J M. Munro Kerr, and Dr G Scott MacGregor.—Dr Carstairs C Douglas read a paper on Some Points in Infant Feeding While recommending maternal nursing as the best, he pointed out that in certain cases where the child did not thrive an analysis of the milk might indicate the error He had found in some cases a reduction in the percentage of fat and in others a diminution in the sugar or an increase in the amount of proteid. Cows milk used without dilution was not recommended as a routine but a dilution to one to three without the addition of cream and sugar (preferably lactose) was too much. The speaker pointed out how the reduction in the fats might interfere with the absorption of the lime salts (as lime soaps) and might thus have some bearing on the etiology of rickets. For the infant fed with cow's milk the milk ought to be pasteurised and absolutely free from preservatives. The treatment of certain cases of infantile indigestion was touched upon and a number of the artificial foods received comment.—The paper was discussed by a number of the Fellows.—Mr. R. H Parry asked about the standard of Glasgow milk.—The President, while thanking Dr Douglas for his interesting paper, stated that he agreed with Dr Munro Kerr in his statement regarding the unsatisfactory nature of the artificial feeding of infants He had not found that undiluted cow's milk always agreed. In some cases he had found marked benefit from the use of a little raw beef juice.—Dr Douglas, in reply, recommended the pasteurisation of milk as this did not interfere with the antiscorbutic property of milk, which was probably due to the living leucocytes which it contained. In reply to Mr Parry he said that he had analysed a number of specimens of milk and had found them quite up to the standard.—Dr Alexander MacLennan read a short note on a case of Large Adenomatous Polypus and showed sections of the tumour and of some other types of polypi.—Dr Munro Kerr read notes on a case of Carcinoma of the Cervix at Term. Cæsarean section was performed (giving a living child) and was followed by supra vaginal hysterectomy This was performed to prevent the very probable onset of sepsis. The patient recovered from the operation but she died from the effects of the carcinoma six weeks after leaving hospital. During the course of the pregnancy Dr Munro Kerr had seen the patient and on finding that the carcinoma was inoperable had decided to perform Cæsarean section in order, at least, to save the child.—Mr Parry instanced a case where he had scraped away the carcinomatous tissue and had delivered the child, which was known to be dead, by craniotomy The mother had recovered from the confinement.—Dr A. W Russell reported a case of Advanced Carcinoma of the Rectum complicating Pregnancy An inguinal colostomy had to be performed and following admission there was a gain of two ounces in weight This treatment was followed for ten days The temperature then suddenly rose to 102° F and the child became very restless Petechiæ were observed on the legs, followed by ecchymoses on both legs and over the sacrum The gums were then noticed to be swollen and soon became spongy and bled freely There was also melæna A scratch which the child received on one of the fingers bled freely During the following day the child was very restless and there was retraction of the head The temperature remained high and the pulse rose to 166 per minute There was no leucocytosis. On the condition being recognised as scurvy the diet was at once changed to fresh cow s milk and lemon juice in glycerine was given freely From this time the child progressed favourably for about three weeks, when she developed a typical attack of measles, followed by broncho pneumonia, from which she died

The diagnosis of scurvy appears to be evident, especially when the feeding and the results of treatment are considered It is very unlikely that in this case the scurvy could have been associated with rickets, as this condition is extremely rare at the fourth month and careful inquiry into the history and examination of the bones after death failed to give any evidence of rickets Nor did the condition correspond to the type described by Sir Thomas Barlow as infantile scurvy, for there were no marked tenderness of the limbs and no loss of power, there were no bone changes and no proptosis, and though there were no teeth the gums were spongy The chief interest lies in the early age at which the scurvy developed, the abrupt onset of the symptoms ten days after the last administration of fresh milk, the sponginess of the gums in the absence of teeth, and the very rapid improvement under anti scorbutic treatment

Newcastle-upon Tyne

A CASE OF SPURIOUS LABOUR.

By JOSEPH A W PEREIRA, M R C S ENG , L R C P LOND

THE patient aged 24 years, was married on August 1st, 1899 A couple of months later I was engaged to attend her in her confinement which was expected to take place on May 1st, 1900 Somewhere about January I was told that the patient was losing blood. Concluding that a miscarriage was impending I recommended rest in bed and suggested that if this treatment did not stop the bleeding I was to be informed of the fact. I heard nothing further until March when accidentally meeting the patient's mother I was told that there was again a little bleeding which was arrested by the same treatment. Exactly on the day appointed I was sent for On arrival I found labour apparently in full progress and the infant's clothes were being aired before a bright fire. The patient herself was in bed, her face buried in the pillows She was pulling vigorously at a jack towel tied to the foot of the bed Her mother and a neighbour were helping on the labour as best they could, one supporting the back and the other buoying her up with cheerful conversation. After being there some minutes I proceeded to satisfy myself that all was right. My astonishment was great when I found the cervix firm and conical I immediately placed my hand on the abdomen It was perfectly flat An invitation to the two bystanders to do the same soon convinced them that we were dealing with a case of spurious pregnancy and labour

The patient belongs to a very neurotic family An elder sister was in an asylum and a younger sister suffers from frequent paroxysms of violent temper The nature of the two losses of blood becomes at once apparent. A noteworthy fact is that the spurious labour came on exactly nine months after marriage.

Exeter

BARNSTAPLE DISPENSARY —The seventy-first annual meeting of the supporters of this institution was held on Jan 29th under the presidency of Sir Bourchier Wrey The medical report stated that during 1902 the patients numbered 2903 The financial statement showed that notwithstanding an increased expenditure the adverse balance of 1901 had been paid off and a favourable balance of £33 remained.

Medical Societies.

LIVERPOOL MEDICAL INSTITUTION

Exhibition of Cases —Infantile Scurvy

A MEETING of this society was held on Jan. 15th, Mr. RUSHTON PARKER, the President, being in the chair

Dr W B WARRINGTON described a case of Acute Ascending Paralysis, usually named after Landry There was a distinct history of an attack of influenza about a fortnight before the onset of symptoms Motor paralysis rapidly developed in the lower limbs and spread to the arms the face, the palate, and the thorax After a stationary period of a fortnight recovery began and became complete. Diaphoretics and morphia were given at first, then ergot, and finally iodide of potassium and mercury The electrical reactions were normal throughout and the integrity of the sphincters was maintained —Dr W BLAIR BELL thought that the case was one of neuritis following influenza. He narrated a case of Landry's palsy which he had lately seen in a girl, aged 20 years. A negative neurological examination had been made by Dr W Aldren Turner —Dr W CARTER said that he had seen two cases of acute ascending paralysis in which the administration of large doses of ergot had done much good, the patients ultimately recovering —Dr T R GLYNN, Dr. A S F GRÜNBAUM, Dr NATHAN RAW, and Dr R J M BUCHANAN spoke, and Dr WARRINGTON replied.

Dr WARRINGTON also described a case of Acute Yellow Atrophy in a young woman who had been nursing a child for 16 months The early symptoms were nausea and vomiting followed by marked jaundice and diminished liver dulness Urea was diminished, but leucin and tyrosin were not present in the urine. The knee jerks disappeared and the patient died from respiratory failure. The duration of the illness was about six weeks —Dr T R. BRADSHAW said that the absence of leucin and tyrosin was no presumption against the diagnosis of acute yellow atrophy, they were absent in a typical case of his own

Dr BUCHANAN showed a case of Aneurysmal Varix between the Left Subclavian Artery and the division of the Left Innominate Vein due to a gunshot wound received in the late Boer war Associated with the varix was left brachial monoplegia with the peculiar condition of flexibilitas cerea of the arm. Dr Buchanan considered that some indirect damage had been done to the nerves supplying the rhomboids and the lower part of the trapezius, although the bulk of the palsy might be functional. He thought that hypnotic suggestion was likely to be of value.—Dr BRADSHAW agreed with the diagnosis of aneurysmal varix He thought that the palsy was entirely functional and the wasting due simply to disuse as there were no deformity and no trophic change in the skin Flexibilitas cerea in one limb was rare, but the hysterical state on which it depended was not very infrequent in soldiers who had been wounded.—Dr BUCHANAN replied

Dr E T DAVIES related a case in which he had removed 1754 Stones from the Gall bladder of a woman aged 51 years There was no definite history of jaundice, but the urine was coloured and the skin was tawny The patient made an excellent recovery

The adjourned discussion upon Dr Peter Davidson's paper on Infantile Scurvy was opened by Mr S KELLETT SMITH, who said that they were handicapped from the onset by their ignorance of the true cause of scurvy There were many theories, but in this country the disease was regarded as the outcome, direct or indirect, of some malnutrition. In the case of adults the anti scorbutic properties of lime juice, which contained certain known salts, was amply proved, but it was false argument to conclude from this that the absence of these same salts from the diet was the cause of scurvy Close examination of the dietary in most cases of scurvy revealed the fact that fats were present in insufficient quantity Bottle-fed babies were especially liable to suffer in this way for while attention was given to modification of the proteids and sugar of cow's milk, little regard was paid, as a rule, to the equalisation of the fatty matter He thought, therefore, that in all cases showing early symptoms of scurvy the diet should be carefully criticised with respect to the proportion a good example of the hydrostatic paradox. It had a small feed pipe—the ileum—and a piston of much larger sectional area in the fæcal column of the ascending colon, the whole forming a kind of hydraulic lift, the gain being equal to about ten times in the ascending colon and twice in the sigmoid flexure. It was just where this power reached its minimum that syphonage came to the rescue. Dr Leftwich showed experimentally that syphonage set up a vacuum in the cæcum, the ileo-cæcal opening being blocked probably by a sucking through of the mucous membrane of the ileum like an incipient intussusception for which lesion a good explanation was thus offered. The formation of a vacuum might have a highly beneficial effect in evacuating the appendix.—A vote of thanks was proposed by Dr F F Caiger and was carried by acclamation.

THERAPEUTICAL SOCIETY —A meeting of this society was held on Jan. 20th when Dr J Gordon Sharp read a paper on Dita Bark (*Alstonia scholaris*) and Australian Bitter Bark (*Alstonia constricta*) two drugs belonging to the dogbane family He also showed specimens of the barks and demonstrated the chemical and pharmacological actions of the crude drugs and their alkaloids. Dita bark was found in India Malay and Australia Strong sulphuric acid applied to the surface gave a characteristic pink colour It contained three alkaloids—ditamine, echitamine, and echitenine, all belonging to one series. The first was the chief, it gave a pink reaction with strong sulphuric acid In frogs it paralysed muscle by coagulating its substance and was found to act like curare in some respects This must not be forgotten, for the neglect of this point might explain why in large doses it had often been found to produce collapse The tree yielding Australian bitter bark was found in Eastern Australia. The bark itself was brown very bitter in taste and aromatic in odour. Strong nitric acid applied to the inner surface gave a dark red reaction, similar to the colour produced by the same reagent on the bark of nux vomica It contained four alkaloids—alstonine (formerly known as chlorogenine) porphyrine, porphyrosine, and alstonidine. Alstonine was the most important of these. Commercial alstonine was mixed with resinous matter and was not crystalline but the pure alkaloid could be made to crystallise. It gave a red reaction with strong nitric acid A solution of the alkaloid in water, as well as a watery solution of the bark, was fluorescent. In its pharmacology it resembled both nux vomica and quinine but it had not so much resemblance to curare as dita bark or its alkaloids. Like quinine it paralysed *Amœba rotifera* &c. On beetles (*Blaps mortisaga*) crickets (*Acheta domestica*), and wasps it acted like quinine. In frogs in medium doses it acted like strychnine, but tetanus was not so marked or so universal. For the full play of symptoms both vessels and nerves must be intact Its final action was to paralyse completely evidently due to excessive activity The therapeutics of the drug had been worked out by the Bancrofts of Australia and by Bixby of the United States It was quite distinct in its action from dita bark and acted on the skin, producing a mild diaphoresis. In the kidneys it increased the volume of the urine and toned up and slowed the pulse. The tincture was especially useful in influenza immediately after the acute symptoms had passed off The Pharmacopœial dose was too large one half of the amount specified was enough and when prescribing the tincture that made from *Alstonia constricta* should be ordered.

BURNLEY AND DISTRICT MEDICO-ETHICAL SOCIETY —A clinical meeting of this society was held on Jan. 8th, Mr S. M. Giffen being in the chair —Dr James Mackenzie read a paper on Pain He defined pain as a *disagreeable* sensation due to stimulation of some portion of the cerebro-spinal nervous system and referred to the peripheral distribution in the external body wall of cerebro-spinal sensory nerves. This definition implied that the sensation of pain, from whatever source the stimulation arose, whether in the brain, in the spinal cord, in the posterior root ganglia of spinal nerves, in the viscera, or in the external body wall, was invariably referred to the peripheral distribution of a sensory cerebro-spinal nerve and that therefore pain was a phenomenon peculiar to the cerebro-spinal nervous system. In the above definition the division of the nervous system into a cerebro spinal and sympathetic was maintained, as the clinical facts pointed to the conclusion that the sensation of pain (and probably other sensations) did not arise from stimulation of the sympathetic nerves unless through the intermediary of the cerebro spinal nerves Reference was made exclusively to the pain and associated symptoms arising from stimulation of the viscera Experimental observations on animals were practically of no avail in determining this question Such experiments as had shown the various organs to have been insensitive proved only that the stimulus employed had not been adequate to produce pain On the other hand, in such experiments as had demonstrated that the stimulus was adequate and where the animal showed symptoms of pain no evidence was available to determine in what region the pain was felt.—Dr R C Holt opened the discussion by speaking of various referred pains which had been accepted as indications of internal disturbance which did not quite accord with Dr Mackenzie's investigations and theories, he also spoke of Sir Frederick Treves's lecture upon appendicitis and his refutation of the inferences connected with McBurney's point, and finally asked for clinical results with regard to labour pains and with regard to sciatica.—Dr A. M. Sinclair and Mr R. C Rodgers also took part in the discussion.

MIDLAND MEDICAL SOCIETY —A meeting of this society was held on Jan 21st, Mr J W Taylor being in the chair —Dr J Douglas Stanley showed the Heart of a Man, aged 47 years. The patient had complained for some time of recurring præcordial pain which also extended down the left arm, of a tendency to faint, and of dyspnœa The cardiac sounds were feeble and short and the pulse was frequent, irregular, and weak. The patient died suddenly and on post-mortem examination extensive chronic aortitis with degeneration of the valves of the left side was found. The myocardium was abnormally tough and showed fibrotic changes At the apex the wall of the left ventricle was very thin and showed a slight tendency to bulge, forming early cardiac aneurysm —Mr Christopher Martin showed a specimen of Unruptured Tubal Pregnancy removed by operation. There was a history of amenorrhœa for two months, followed by irregular hæmorrhage for three weeks, cramp-like pains in the right side of the pelvis, and the passage of a decidua On examination a large sausage-shaped swelling could be felt behind and to the right of the uterus Mr Martin opened the abdomen and found the right Fallopian tube much enlarged and distended with clot. The fimbriated end was occluded and glued to the ovary There was no trace of old or recent blood in the peritoneum The case was evidently one of tubal pregnancy with intra tubal hæmorrhage. The patient made an excellent recovery from the operation.—A paper by Mr C G Higginson (read in his absence by one of the secretaries) dealt with the treatment of Status Epilepticus The writer drew attention to the use of chloral in repeated doses and referred to cases that came under his own observation where lives had been saved by this method.—Dr C E Purslow read a paper on Abdominal Hysterectomy

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND —A meeting of this society was held on Jan. 28th Dr J H. Stowers the President, being in the chair —Mr G Pernet showed a patient who in addition to Lupus Vulgaris of the Neck, suffered from Deep-lying Nodules in the Forearm and in other parts These he regarded as tuberculo-gummata, but several members expressed the view that they were lipomata.—Dr T D Savill showed a case of Morphœa in a Woman and a case of Facial Hemiatrophy (morphœa facialis) associated with trophic disorder of the eyeball on that side and scleroderma of the scalp —Dr E. G Little showed (1) a case of Morphœa of the Leg, (2) a case of Congenital Urticaria Pigmentosa of the Nodular Type, (3) a case of Urticaria Pigmentosa of the Macular Type also dating from birth, (4) a case of Urticaria Bullosa in an Infant (many members objected to this name and regarded the case as an erythema), (5) a girl suffering from an Eruption on the Legs which he placed in the tuberculide class (there was no evidence of tuberculosis in this case or history of the same), and (6) a boy suffering from Extensive Leucoderma and Melanoderma, the greater part of the scalp being also affected.—Dr A Eddowes showed a case of Lichen Planus and the case of extensive Lichen Planus affecting the Scalp and whole of the Body exhibited by him at the last meeting of the society together with Microscopic Sections of the Skin.—Dr. G N Meachen showed (for Dr Abraham) a case of Urticaria with Pigmentation The view was expressed that a scraping should be examined for the microsporon furfur —Mr T J P Hartigan showed a case of to avoid the danger of performing a Cæsarean section after an artificial anus had been established, the uterus with the child in it was removed at the sixth month. Dr Russell did not think that it would have been justifiable to deliver the fœtus by the vagina on account of the risks of tearing the rectum , the disease had also invaded the vagina —Mr Parry, who had performed the hysterectomy on this patient, concurred with these views and did not think any other treatment would have been advisable

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION —A general meeting of this society was held on Jan 30th, Dr V H Wyatt Wingrave, the President, being in the chair —At the President s request the secretary read a letter from Mrs Lennox Browne in reply to the letter of condolence sent her in the name of the association on the occasion of her husband's death —The President then referred in suitable terms to another loss which the association had sustained in the death of Dr G Hunter Mackenzie, and it was agreed to send a letter of condolence to his widow —The exhibition of cases followed and among them were the following Mr W Stuart-Low Cases showing the Beneficial Action of Mucin in Atrophic Rhinitis —Dr P H. Abercrombie testified to the great benefit derived from the treatment by several of his hospital patients.—Mr J Stewart Mackintosh also spoke in favour of the treatment and referred to its beneficial action on the stomach and bowels and the relief of pain in malignant disease of the rectum.—Dr L H. Pegler inquired as to the *modus operandi* of mucin.—Dr Wylie had seen good results in several cases of atrophic rhinitis treated with mucin.—Dr W Jobson Horne suggested that the massage employed with mucin might account for part of the good result obtained, and asked how the internal administration of mucin could affect atrophic rhinitis —The President congratulated Mr Stuart-Low on his results with mucin He thought that not enough time had yet elapsed for the treatment to have had a thorough trial. The good effect on digestion he regarded as of great importance He suggested that the alkali present in the tabloids of mucin might have something to do with the good results —Mr Stuart-Low, in replying, thanked the Fellows for the great interest taken in the subject and described the *modus operandi* of mucin to be local and general It inhibited bacterial growth and was hygroscopic and cleansing and it supplied the natural moisture which was defective in these patients He admitted that the massage carried out by the surgeon was beneficial but cases had benefited markedly without the massage and only with mucin Mucin acted as a protective coating to the stomach and it was the natural protector —Dr Abercrombie Two cases of Adhesion between the Soft Palate and the Posterior Pharyngeal Wall, the result of Tertiary Syphilis, operated on with good results —Dr E D Vinrace thought that the openings would gradually lessen in size as time went on —Mr W J C Nourse said that considering the great discomfort arising from the nasal obstruction in such cases he thought it wise to do all in one s power to give relief, and he thought systematic dilatation of the openings might be advisable —The President congratulated Dr Abercrombie on the good results following his operation and remarked how much relief might be obtained in such cases with even very small openings —Dr Pegler showed cases of Deflected Septum, treated by Moure s operation together with the septotome devised and used by Dr Pegler —Dr J Dundas Grant congratulated Dr Pegler on the excellent results obtained He regarded it as a distinct gain to correct the deformity without making a septal perforation.—Dr Jobson Horne regarded Dr Pegler's instrument as better than the original one

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN —A meeting of thi society was held on Jan. 16th, Dr G E Shuttleworth being in the chair —Dr G A Sutherland and Mr J W Thomson Walker contributed a paper on a case of Syphilitic Endarteritis and Nephritis in an Infant. The child presented evidence of congenital syphilis and there was paralysis, and later rigidity of the right arm the lower extremities also becoming rigid and the head retracted. Albumin was present in the urine At the necropsy there were endarteritis of the cerebral arteries and softening of the left frontal lobe of the brain The kidneys showed diffuse interstitial nephritis. A second case of interstitial nephritis due to congenital syphilis was also described Dr Sutherland and Mr. Walker considered that the most important change in this form of arteritis took place in the adventitia and that syphilitic arteritis was a secondary and not a tertiary manifestation of the disease. The etiology of nephritis in children was often obscure and the importance of syphilis as a cause was greater than was usually supposed. Many of these cases were probably unrecognised owing to the slight naked-eye changes —Dr Leonard G Guthrie considered that the views expressed by Dr Sutherland and Mr Walker bore out his own opinion—namely, that chronic interstitial nephritis in children was often due to syphilis —Dr G Carpenter mentioned two cases of the kind that had been under his care.—The paper was also discussed by Dr Shuttleworth and Dr R Hutchison.—Dr Sutherland and Mr Walker replied.—Mr Walker showed specimens of (1) Traumatic Cephalhydrocele , and (2) Punctured Fracture of the Skull —Mr Sydney Stephenson described a case in which Paralysis of the Cervical Sympathetic on one side had closely followed the evacuation of a Retro pharyngeal Abscess by Hilton's Method. The symptoms were characteristic and included ptosis, contraction of the pupil, enophthalmos, and lowered intraocular tension No changes in the state of the blood vessels or the function of sweating were noted.—Dr Guthrie showed an infant, aged five months, suffering from an unusual kind of Microcephaly The occipital bone showed a beak like projection and overlapped the two parietal bones There was in addition spasticity of all the limbs. The child s features did not suggest imbecility —Mr A. H. Tubby entered a protest against operating in such cases His experiences in that direction had been uniformly unfortunate Craniectomy appeared to be powerless to cure the condition —Dr Charles W Chapman read notes of a case of Dilatation of the Stomach in a girl, eight years of age, who had been accustomed to take unsuitable food at irregular intervals. Under suitable treatment she made a complete recovery —Dr Carpenter read notes of a case of Acute Primary Thyroiditis in a rachitic infant, aged 14 months. The disease went on to suppuration, the abscess was opened, and the patient recovered Dr Carpenter called attention to the rarity of the condition, even as a complication of the specific fevers, and pointed out that in some reported cases induration of the gland, and not suppuration, had resulted as the sequel of inflammation.

BRIXTON MEDICAL SOCIETY —At a meeting of this society held on Jan 29th, Dr Patrick G Simpson being in the chair, Dr R. W Leftwich read a paper on the Mechanism of the Large Intestine He pointed out that the structural peculiarities of the colon were all adverse to the view that peristalsis there was the one propelling force. The large lumen, the weak muscular development, the sacculation of the walls, the fixation and the upward course of the ascending colon, all presented obstacles. In cases of orthopnœa a stream had to be forced against gravitation for months together without the help of valves, and yet constipation was not a special feature of the condition Dr Leftwich then proceeded to demonstrate that there were two other forces at work The 'course of the large intestine suggested a syphon, its short ascending limb, starting from the right iliac fossa, being the ascending colon, and its long descending limb, terminating at the anus being the descending colon and rectum. There was, therefore, always a fixed fæcal column in the colon, the cæcum being usually empty After defecation the stream propelled by peristalsis of the small intestine filled the cæcum and on reaching the fæcal column, pushed this forward and disturbed the balance , syphonage was then set up, the cæcum was emptied, and the rectum was filled The necessary rigidity of the walls of the colon was obtained by a tonic contraction of the longitudinal bands which also deepened and thickened the dissepiments between the saccules The existence of this tonus was shown by the deep retraction of the anus—the longitudinal fibres of the rectum being continuous with those of the bands , by the maintenance of the transverse colon *in situ* without waviness notwithstanding that it was twice as long as its bed , and by the elongation of the colon which took place in sigmoid obstruction The tension upon the bands and the unequal distribution of gas and solids in this condition accounted for the movements which had been mistaken for peristalsis The saccular undulations described by Boas must be quite ineffective for propulsion and were connected with absorption only Further, the cæcum presented

Insomnia will repay perusal, as will also the chapter on Epilepsy Dr Yeo extols the administration of bromides in this affection, and with regard to the appropriate dose he rightly maintains that we must study each case that comes under observation and note the individual susceptibility to the drug and regulate the dose accordingly, some individuals will be found to require much larger doses than others. The remaining part of this volume contains instructions on the Treatment of Constitutional Diseases (gout, diabetes, rheumatoid arthritis) and of the Specific Infective Diseases

We can speak in the highest terms of praise of this publication and strongly recommend a study of it to all practitioners and senior students

---

Diet and Food, considered in Relation to Strength and Power of Endurance, Training, and Athletics By ALEXANDER HAIG, M.A, M.D Oxon, F R.C P Lond. Fourth edition, with seven Illustrations. London J and A Churchill. 1902. Pp 127 Price 2s

Avenues to Health. By EUSTACE H. MILES, M A. London Swan Sonnenschein and Co 1902. Pp 438 Price 4s 6d

The Art of Breathing as the Basis of Tone Production. By LEO KOFLER, Teacher of the Art of Singing New York City London J Curwen and Sons. 1902. Pp. 277 Price 4s

THESE three little books may well be criticised side by side, for the first two deal mainly with the question of health by way of the alimentary canal and the third with health by way of the respiratory apparatus Dr Haig's views are too familiar to require here any fresh exposition. That in a great number of cases a large proportion of his statements hold true we have no doubt We have equally little doubt that he allows too little for other injurious influences upon the metabolism of the body than the ingestion of improper nitrogenous food stuffs There is, at any rate, this great advantage about Dr Haig's writing It clearly states a clear issue His view reduces all men and women to mere automata illustrating this simple principle—nine ounces of albumin per pound of body weight if they are to keep in perfect health. If we do not agree with the precise working of Dr Haig's human machine nothing can be easier than to say so and to give reasons why

With Mr Miles the case is very different, though the aim of his book is much the same. Mr Miles's description of health, however, is so far reaching, and he includes so many only slightly cognate spiritual conditions, that we are not to expect the precise conclusions of Dr Haig Mr Miles would appear to consider a person unhealthy for instance, who does not enjoy good music or a dance. Yet men of unexceptionable bodily condition may not find any pleasure in the one or trouble to acquire the practice of the other No doubt Mr Miles's sketch of a healthy man presents us with a being uniformly endowed with a level excellence of mental and physical qualities But we cannot admit that everyone less happily gifted is therefore to be called unhealthy Some of Mr Miles's principles land him in quaint conclusions and as he possesses the enthusiast's fixity of gaze the humorous side of his own picture does not catch his eye. Thus on this same question of dancing we cannot read without an amused image of what would occur in the ordinary ballroom were Mr Miles's doctrines enforced that "after the dance there should be cold sponging and rubbing" Broadly speaking certainly most of Mr Miles's recommendations are admirable, particularly when he advocates fewer and simpler meals and regular devotion to simple but various bodily exercises

Mr Kofler's book has the merit of being the outcome of long actual experience. Here and there it shows the disadvantages arising from defective training in physiology, but on the whole it is a valuable little work and should be studied by actors, singers, and public speakers with great benefit to themselves.

LIBRARY TABLE

Annals of Ophthalmology Vol. XI, No 4 1902. H. V WÜRDEMANN M.D, Managing Editor Pp 209 Published quarterly by Jones H. Parker, St. Louis, Missouri, U S A. Price $4 per annum in advance —This part of the *Annals of Ophthalmology* contains several interesting articles, amongst which may be mentioned the following —1. A Study of the Connective Tissue of the Orbit by a New Method, by Lucien Howe, M D, of Buffalo, New York. The author of this article recommends the hardening of the orbit and of its contents in Zenker's fluid for several days, then decalcification by means of cotton wool moistened with 20 per cent. hydrochloric acid wrapped round the bony walls, and finally staining with Gerson's picro-fuchsin stain or with Mallory's phosphomolybdic-acid aniline blue. The mode of insertion of the recti muscles is illustrated by reproductions of photographs which, however, leave much to be desired in point of clearness. 2. J P Nuel, M.D, of Liége, on Toxic Amblyopia This article is translated by F W Marlow, Professor of Ophthalmology in the University of Syracuse, New York. Professor Nuel holds that both the optic nerve and the retina are implicated in the morbid process associated with alcohol nicotin amblyopia and maintains that the inflammation is of a parenchymatous nature. 3. Alexander W Stirling M.D, C M Edin., gives an Analysis of 100 Cases of Refraction with Special Reference to Headache. 4 George F Keiper, M.D, La Fayette, Indiana, contributes a paper entitled "When to Operate for Ripe Senile Cataract in one Eye, the other Eye possessing useful vision" The author argues that the patient if successfully operated on has a larger field of vision which is a source of protection from accidents the cause of which may be due to the blind side, that the dangers and difficulties of extracting an over-ripe lens are avoided, that the patient has continuous vision since the other eye is not usually affected, that he has more comfort with vision in both eyes, and finally that his appearance is better Additional arguments might be advanced that in case of failure there is less disappointment on the part of the patient as he can still see well and that important information in regard to the habits or peculiarities of the patient is sometimes obtained from the first operation. 5 M. V Ball, M.D, of Warren, Pennsylvania, gives the details of a case of Death from Meningitis following Enucleation of the Eyeball. 6 H. V Würdemann, M D Milwaukee, Wisconsin, has an article on Papillomatous Degeneration of the Conjunctiva The rest of the part is occupied with abstracts of English, colonial, and foreign literature.

Response in the Living and Non living By JAGADIS CHUNDER BOSE, M A. D Sc, Professor, Presidency College, Calcutta. With 117 Illustrations London Longmans, Green and Co 1902. Pp 199 Price 10s 6d —Under this title Professor Bose has assembled together several interesting papers which deal chiefly with the small electromotive forces which can be detected in various living tissues and which have long been known in the case of nerve and muscle preparations as the currents of rest and the negative variation or current of action The study of these phenomena has been extended by the author to vegetable tissues and also to inorganic substances, and it is part of the object of this book to show by records and tracings the electro-motive forces which are set up in metallic wires when they are subjected to various mechanical and chemical influences Professor Bose points out the remarkable similarity between these tracings and those obtained with living tissues under analogous treatment He draws the inference that there is no necessity for the assumption of vital force to account for these "phenomena of response' and he ascribes the electro-motive effects which are manifested in animal and vegetable tissues as well as in the metallic wires experimented with to physico chemical action solely Professor Bose's work raises the

Tuberculous Folliculitis —Mr A. Shillitoe showed an extensive Nodular Syphilide and a case of Lichen Planus Circinatus.—Dr W B Warde showed an old man with Lupus Vulgaris affecting nearly the whole of the Face and Scalp

EDINBURGH ROYAL MEDICAL SOCIETY —A meeting of this society was held on Jan 30th, Dr Watson being in the chair —Dr Wilson showed the following card specimens (1) Photographs of patients suffering from Paralysis Agitans, Molluscum Fibrosum, and Syringomyelia, (2) Photographs demonstrating Tuberculous Pericarditis, and (3) a Microscopic Specimen of Acute Lymphatic Leukæmia with Streptococcic Poisoning —Dr A. M. Malcolmson showed a large Aneurysm of the Aorta.—Dr R. Dods Brown read notes of a case of Acute Lymphatic Leucocythæmia which occurred in a schoolboy, aged 13 years, who was admitted into hospital suffering from bleeding from the nose, gums, and throat. While in hospital the patient had hæmatemesis, hæmaturia, and melæna, and he died about a fortnight after admission. The post-mortem examination showed marked hæmorrhages throughout the body Dr Brown exhibited sections of the various organs, also microscopic sections of the spleen, thymus, and bone marrow The thymus gland was very much enlarged and the microscope demonstrated that it was crowded with lymphocytes —Dr A B Ross read notes of two cases of Diabetic Coma both of which were fatal The coma occurred in middle aged women and diacetic acid and acetone were present in the urine in both A post-mortem examination was made in one case and the pancreas was found to be slightly cirrhosed and the stomach showed acute inflammation —A communication on a case of Spina Bifida by Dr Hey was read in his absence by Dr Wilson. The case occurred in a girl six years of age and was successfully operated on.—A dissertation on the Diagnostic Value of the Examination of the Blood by Dr J H Montgomerie Bell was read in his absence by Dr A. H. Firth

PATHOLOGICAL SOCIETY OF MANCHESTER —A meeting of this society was held on Jan 21st, Mr Broadbent being in the chair —Professor S J Hickson described some Deformations of Corals produced by Animal Parasites and exhibited specimens and photographs illustrating the various phenomena mentioned —Mr Smith showed the specimens from two cases of Intussusception of the Small Intestine, one of which had originated as an intussusception of a Meckel's diverticulum —Mr A. J Rodocanachi exhibited and described a specimen of Paget s Disease of the Nipple.—Dr Philip Prebble and Dr W E Fothergill described the specimen from a case of Calculous Pyonephrosis

Reviews and Notices of Books.

A Manual of Medical Treatment or Clinical Therapeutics By I. BURNEY YEO, M D, F R C P Lond., Emeritus Professor of Medicine in King's College, London, Consulting Physician to King's College Hospital, Hon Fellow of King's College, formerly Professor of the Principles and Practice of Medicine and of Clinical Therapeutics in King's College. New and revised edition In two volumes. London Cassell and Co, Limited. Pp Vol. I 696, Vol. II 818 Price 21s

THE object of this work is the study of disease from the point of view of treatment. The author explains in his preface that the teaching of therapeutics is in his book approached from the side of the disease and not from the side of the drug or remedy It is by examining into the mode of causation of disease by investigating the true nature of the morbid changes which underlie the phenomena of disease, and by an exact knowledge of the properties and mode of action of the agencies that are administered for the purpose of favourably influencing its course that what are termed rational indications for treatment are arrived at Dr Yeo, therefore, has attempted wherever it was possible, to deduce rational indications for treatment from an examination of the pathological nature and the clinical course and characters of the disease under discussion For the purposes of practitioners and students this is certainly the most advantageous plan to adopt and that Dr Yeo has succeeded in his endeavours we think will be allowed by every reader of this manual. The etiology and symptoms of disease are considered in terse, concise terms which convey a large amount of information, but for a full clinical description text-books on general medicine must, of course, be consulted. Selections of formulæ are added to most of the chapters for the purpose of giving completeness and breadth of view to the subject.

Part I. is devoted to a consideration of the treatment of Diseases of the Organs of Digestion. When first entering on private practice the young medical man will be surprised to find how large a number of patients will present themselves suffering from some form of indigestion The treatment of such cases will consist partly of dietetic measures and partly of the administration of drugs, but the course to be adopted in any particular case will be by no means easy to decide Dr Yeo's remarks on acute and chronic gastric catarrh, dilatation of the stomach, and dyspepsia will be found of the greatest value in dealing with these conditions. The directions given as to diet are very lucid, and the many hints as to treatment by drugs, together with the large number of formulæ, make the chapters devoted to diseases of the digestive organs most valuable for reference. The section on Modern Gastric Methods will also be read with interest. Dr Yeo very wisely deals only with the chief clinical types of gastric disorders and avoids the consideration of the various subdivisions and forms of dyspepsia as set forth in some recent treatises on gastric diseases—such as "achylia gastrica," "neurasthenia gastrica," "gastrosuccorrhœa," &c. Certain methods of investigation and treatment of gastric disorders, however, which are fully described in the works just referred to, are considered, such as the examination of the contents of the stomach after the administration of test meals We agree with Dr Yeo that too much reliance must not be placed on the inferences that are drawn by some physicians from the results of such analyses A detailed examination of the chemistry of the gastric secretion must be left to the chemist skilled in pathological analyses and can hardly be satisfactorily conducted by the practitioner

Diseases of the Heart and Blood vessels and of the Blood and Ductless Glands are dealt with in Part II. We strongly recommend a study of these pages to young practitioners The remarks on cardiac tonics are excellent Due stress is laid on the importance of diminishing the mechanical work of the heart, for this point in the treatment of cardiac affections is apt to be forgotten and the heart may be unduly stimulated by digitalis. Much better results are often obtained by the administration of vaso-dilators, especially when there is degeneration of the cardiac muscle The chapter on the Management of Special Symptoms dependent on Chronic Valvular Disease also contains many valuable hints as to obtaining relief from the distressing symptoms which may accompany a failing heart.

Parts III. and IV of the first volume are devoted to a consideration of the Treatment of Diseases of the Organs of Respiration, including pulmonary tuberculosis The same high standard is maintained as in the earlier chapters of the book

In the second volume the chapters devoted to Diseases of the Liver contain sound advice. For instance, some cases of "catarrhal jaundice" prove difficult to manage, Dr Yeo suggests several measures which may be adopted in such circumstances. The Treatment of Diseases of the Nervous System is very carefully discussed, but we have not space to deal fully with the many chapters occupied by a consideration of this subject. The remarks on the Treatment of ll cases comparable with those of the sanitary districts h they have replaced, so that the amount of local crowding at the two periods cannot be uniformly rasted Mr Shirley Murphy has however given ible which contains full particulars as to overcrowd in tenements of less than five rooms in each he sanitary districts of London. According to the res given overcrowding as measured by the proportion he population living more than two in a room, is excepally prevalent in the areas constituted by the eastern central groups of boroughs, in which areas, we observe, perhaps mainly for the foregoing reason, the rate of tality is constantly excessive and higher than in any r part of London It will be noticed that in Lewisham, re only 3 5 per cent. of the population occupy tenements ne room the death rate, corrected for age-constitution of population, does not exceed 13 4 per 1000 living whilst Holborn, where the proportion occupying single-roomed ements averages 27 per cent the corrected death rate is 7 per 1000 Again, the proportion of population living two-roomed tenements was equal to 32 7 per cent in sbury, where the corrected death rate averaged 23 1 per 0 (the highest in London), whereas the proportion in iting two-roomed tenements in Hampstead, which isters the lowest death rate in London, does not exceed 7 per cent.

Of the health of the metropolis as a whole in 1901 Mr rley Murphy has a satisfactory account to give. Judged the general mortality from all causes, uncorrected for age-l sex distribution of population the year 1901 was the lthiest on record, the death rate from all causes being ly 17 1 per 1000 of the population. Compared with the vious decennium, the London death rate in the year erred to was considerably lower at each age period of life d for each sex. The mortality from epidemic diseases in e aggregate showed a decided reduction and so did that m pulmonary and other forms of tuberculosis. The e disease which formed, as in previous years a serious ception to the rule, is cancer which accounted last year r a mortality considerably in excess of even the high cennial average. In order to ascertain the true local cidence of fatal cancer in relation to population a useful ble is for the first time inserted in this report, showing the tual number of deaths from cancer which rightly belong each metropolitan borough, after due distribution of the aths taking place in hospitals and workhouses

With commendable promptitude, which other authorities ight with advantage emulate, Mr Shirley Murphy has cluded in his report an extended life table by means of hich the error attaching to ordinary death rates, by ason of differing age-constitution of population may be minated. In a table at p 13 the number of deaths that tually occurred in the year 1901 at each age period and for ach sex is compared with the number of deaths that would ave occurred had the rates of mortality in the previous ten ears been maintained throughout 1901. The number of ves gained in the latter period is also shown, and this gain s exhibited in terms of "life capital," which is obtained by pplying the mean future lifetime (from the life table) to the umber of lives saved at each age-group Thus we learn hat in the year 1901 there has been a saving of 9289 lives n London representing a gain to the community of 337 635 ears of life capital. In the metropolis as in all large rban communities the age-distribution of the population s seriously affected by migration, but Mr Shirley Murphy oints out that in London, at any rate the immigra ion of young adults exercises a favourable effect n the death rate For this factor however the life able affords only a partial correction. In so far as migration disturbs the age-distribution of the population its ffects are compensated for by the life-table method and no llowance need be made in this direction for the effects of migration, but these effects are not limited to a mere disturbance of the composition of the population in regard o sex and age and it will readily be understood that the verage immigrant who probably comes to London from he country is likely to be healthier and more robust than he average dweller in towns Migration therefore must be looked upon as probably altering the character at least as much as the age-constitution of the population, and the life-table method cannot adequately compensate for disturbances of this nature. In order to exemplify the effect of migration a table is given in the report showing the expectation of life and the probability of living one year at certain ages (1) in London and (2) in the so-called "healthy districts" of the Registrar General. Migration, however, in London appears to be a diminishing factor for the proportion in the total population of London born persons is steadily increasing year by year The proportion of London born females is smaller than that of London born males—a fact which may probably be accounted for by the immigration of females belonging to the class of domestic servants. The influence of the influx of healthy lives is well shown in the table referred to, and this process appears to affect the figures relating to females more than those relating to males. It further deserves to be mentioned that a larger proportion of females than of males probably return to their homes in the country when overtaken by sickness or by advancing age.

Looking Back.

FROM

THE LANCET, *SATURDAY*, FEB 5, 1825.

MATERIA MEDICA.

Pangline, or the active principle of the Sarsaparilla

THE science of vegetable chemistry has been brought to great perfection by the French physicians and their discoveries have induced the chemists of other countries to apply themselves to the investigation of the different natural productions used as remedial agents. The advantages which have already accrued to the profession from the discoveries of the quinina, and the salts of opium have been exceedingly great, and there is no doubt that every article of the materia medica might have its active properties extracted if a careful analysis were made Sarsaparilla has long been known to the public as a very useful remedy for various diseases, and it has lately been made the subject of examination by M Galileo Palotta, an Italian physician, who has discovered in it that which he considers its active principle, to which he has given the name of pangline.*

REVIEW[1]

A full account of the system of Friction as adopted and pursued with the greatest success, in cases of contracted joints, lameness, &c, &c By WILLIAM CLEOBUREY, M.R C S., &c. 8vo pp. 170 Oxford, 1825 Third Edition.

Our author has cited two or three cases of contractions following disease of the knee and hip-joint, one of which we shall insert

'Martha Mayland 16 years of age, or thereabouts, had been for a considerable time under the care of several surgeons for what was supposed to be a disease of the hip joint. Blisters, &c. had been applied, and when I first saw her she had an immense issue in the neighbourhood of the hip joint. This I directed to be immediately healed, and it was my intention, as soon as this was done, to proceed in the manner described in the former cases, but here I was anticipated in my practice by a noted bone setter I believe Mr Thurland of Charlton,† who laid hold of the limb, and extended it in a similar manner The result was the same - the girl recovered the use of her limb

---

* M. Miquel, the editor of the *Gazette de Santé* from a number of which publication (Jan 5) we have taken the substance of this account, has adopted a curious species of etymological reasoning in his attempt to trace the origin of the word *parigline* he says "*déduit sans doute du nom latin de la plante* smilax sarsaparilla." This is like the assertion of a learned bibliographer who said that *alfana* came from *equus*, but admitted, at the same time that it had changed its character in the descent —ED L.

† This gentleman generally intoxicated his patients previous to the operation and his method of effecting the separation of adhesions situated round the head of the femur was as follows:—He placed the patient on a bed with her face downwards and made the pelvis a fixed point by kneeling with one knee on the sacrum He then passed his right arm under the femur and making a lever of it forcibly extended it backwards towards the ear till the adhesions gave way In this manner he succeeded in nine cases out of fourteen which had baffled the regular practitioners. The other five he had too much prudence to attempt, as the joints were either under the immediate influence or effect of inflammation or portions of bone had exfoliated from them, indicating that anchylosis had taken place.

Mr Thurland is now dead and was the last of a family who had practised this art for nearly a century question whether the electrical phenomena of nerve and muscle are to be regarded as of prime importance or not Possibly they represent merely a minute waste of energy and are, so to speak, accidentally associated phenomena rather than integral factors in the chemical and physical changes which accompany conduction in nerve and contraction in muscle.

[1] Only a portion of the review has been transcribed.

Indstilling fra Beri Beri Komiteen (Report of the Norwegian Beri beri Committee) Christiania 1902 Pp 160 — This is a report of the Royal Commission appointed by the King of Sweden and Norway to examine and to report upon the means of treating and of preventing beri beri on Norwegian ships It contains consular reports reports of masters of ships, and a careful analysis of many points which have been believed to be important in the study of beri beri. With the report we have received a letter from the President of the Commission, Professor Uchermann, who expresses the opinion that beri beri is an intoxication by tainted animal or vegetable food (on ships especially by canned food, in Asia mainly by tainted rice), and that it is not a specific infectious disease The report is interesting and parts of it are in English

Electricity in Medicine and Surgery including the X Ray By WILLIAM HARVEY KING, M D With 116 Illustrations New York Boericke and Runyon Co Pp 296 —This book is divided into two parts which are paged separately The first deals with apparatus, with x rays, and with physiology and diagnosis, and the second treats of electro-therapeutics proper The whole book is characterised by a want of conciseness in description and the treatment of many of the subjects is very inadequate. The account of the reaction of degeneration is poor and without originality Under the heading of Incontinence of Urine no reference is made to the condition of nocturnal enuresis, which is so favourable a subject for electrical treatment. The important subject of the treatment of injuries of nerves (including division of nerves) has one page devoted to it and what is there said of the two quoted instances of divided nerves is almost ridiculous Under the heading of Infantile Paralysis the author states that the application of faradism for purposes of treatment in this disease is incomprehensible From what is written on the subject of the electric bath it is clear that Dr King has no practical experience of it Wehnelt's electrolytic interruptor is a 'strange little instrument" and the description given of it is not precise, and so on. Incorporated in the book is a chapter by Dr Freudenberg of Berlin on Bottini's operation for the treatment of enlargement of the prostate It occupies 47 pages and is well written and good

The Amateur's Greenhouse a Complete Guide to the Construction, Heating and Management of Greenhouses, the Propagation and Cultivation of Plants adapted for Growing therein, with a Description of the Insect, Animal, and Fungoid Pests affecting Plants, and Remedies for their Eradication By T W SANDERS, F L S, F R.H.S, editor of *Amateur Gardening* and *The Profitable Farm and Garden*, author of the "Encyclopædia of Gardening," "Cultivated Roses," &c Illustrated. London W H. & L. Collingridge. Pp 386 Price 5*s* net —This is practically a new work, although it is founded on one by the late Mr Shirley Hibberd In the first place Mr Sanders rewrote the chapter on greenhouse construction for a new edition of the old book and when the present edition was wanted the rest of the book was rewritten "The Amateur's Greenhouse" in its present form is a practically written illustrated volume which should prove of great use to amateur gardeners, and especially to those who do the work themselves. The author's experience as the editor of *Amateur Gardening* has been of great service to him in showing on what particular points information is chiefly wanted by a large and increasing class of readers who love flowers but have not at their command large sums of money to spend on them, while they yet have sufficient time at their disposal to give them a good deal of their personal attention The first part of the book furnishes a description of the construction of greenhouses and of the different methods which may be adopted for heating these structures, a section is devoted to general rules as to the management of greenhouses, and this is followed by an extremely good chapter on the propagation of plants Greenhouse pests are described in a few pages and this section might advantageously be extended. The main part of the volume is occupied by a description of popular greenhouse plants, arranged alphabetically—a plan which has obvious advantages and no less obvious disadvantages, but is probably the best which could be adopted for a work of this kind. Many of the illustrations of the plants are taken from photographs, they are of unequal merit but most of them are good. The few remarks on grafting are not particularly helpful. The modes of grafting are not illustrated and the description of the operation is meagre. Many of the directions given as to the selection of plants and the way of growing them are admirable, there is, for example, some sound advice on the growing of annuals in pots, which will be found most useful to amateurs who have only a very limited space at command, and it is to such readers that the work will prove most useful.

TENTH ANNUAL REPORT (FOR 1901) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON

SECOND NOTICE.[1]

THE housing of the London poor is one of the "burning questions" which the London County Council has for years past endeavoured, hitherto not altogether successfully, to solve, but it is as a matter vitally affecting the public health that Mr Shirley Murphy systematically devotes to this question so large a share of his attention.

A special and novel feature in the present report is the attempt to classify the population of London, not, as is commonly done, according to the mere density of dwelling-houses on area, but according to the degree of aggregation of persons in each room and according to the proportion of one, two, three-, and four roomed tenements in the several districts compared. This has been possible solely on account of the mode of publication of the census returns which were issued complete for London at an early date. The report contains two important tables showing the amount of overcrowding existing in the county of London as a whole in the years 1891 and 1901 respectively, the differences in area between the present "administrative county" and the former "registration county being so slight as scarcely to affect the results. Tenements of less than five rooms have diminished in number, the fall being particularly apparent in the case of single-roomed tenements The average number of occupants per room has also declined in all classes of dwelling, but the greatest decline has again been manifest in the case of tenements of only a single room The relative number of so-called 'overcrowded tenements' and also the number of their occupants in the poorer parts of London showed a considerable reduction in 1901 as compared with the previous census year Speaking generally, we learn that a considerable improvement has taken place in the manner in which the people of London were housed in 1901 in comparison with 1891, in other words, over crowding in the metropolis as a whole has declined during the last 10 years, both in quantity and in intensity Unfortunately, as a consequence of the changes in boundary which have taken place under the London Government Act of 1899 the areas of the present metropolitan boroughs are not as then the endeavour to seek for a satisfactory xplanation of the occurrence of pernicious anæmia nd it was found that when all etiological factors had een *exhausted there still remained a residue of "idio-athic"* cases. Now we learn that the only condition ntitled to be termed "pernicious anæmia" is just that hich was neglected by those observers and that it alone ossesses a single and well defined etiology It is in the lemonstration of this definite character that so much is wing to Dr HUNTER, and we doubt not that by following p his line of inquiry much will be gained, not only in the irection of clearness of conception, but in the treatment of his grave disease.

Multiple Pregnancies

THE subject of prolificacy and multiple pregnancy has always excited the greatest interest amongst both ancient and modern writers We find ARISTOTLE, who thought that the population should be fixed as regards numbers, recommending legislation to prevent its increase and, as he thought, the consequent deterioration of the race. Whether we regard multiple pregnancies as a result of heredity, or as an example of atavism, or merely as a consequence of undue prolificacy, we are confronted with problems of much interest. It is, indeed, only of late years that our knowledge of the laws of fecundity have been based upon well ascertained facts. The influence of heredity in the production of multiple births has long been a matter of popular belief, and the investigations of numerous observers have shown that this belief is well founded. GOEHLERT, from a study of genealogical tables which enabled him to ascertain the fruitfulness of certain families throughout several generations, has found that the tendency to the production of multiple pregnancies is undoubtedly transmitted from parent to child, and that the hereditary influence is decidedly greater when not only the mother but also the father are members of such prolific families Dr J W BALLANTYNE has published some most interesting cases of this kind, in which the relationship between large families and multiple births are well shown. One of the most striking is that of a woman who had 22 children in 18 confinements—four times twins and 14 single births, one of *her sisters had had triplets* and another had given birth to twins The influence of the male parent has been pointed out by GOEHLERT and is illustrated by the case recorded by MERRIMAN It is that of a woman who had 21 children in seven successive births. They were all born alive and 12 survived. That some of the credit for this extreme fecundity may justly be ascribed to the father would seem to be shown by the fact that a female servant seduced by him gave birth to triplets who lived for three weeks. LEROY quotes the case of four brothers in whose family twin pregnancies in the parents of a collateral branch had been observed. All four were the fathers of twins, three of them twice each and the fourth four times Possibly this record afforded the *foundation* for the story of the French family, the male members of which had acquired such a reputation as the fathers of twins and triplets that after a time no woman could be found who would consent to marry any one of them. If we may accept the observations of HELLIN it would appear that the occurrence of multiple births is directly connected with a relatively large number of egg follicles in the ovary and is due to a persistence of the embryonic condition of that organ in which the number of follicles is very much greater than it is at subsequent periods of life The chances of triplets surviving are but small. RUPPIN has calculated that the mortality of the children in twin pregnancies is double and in triplet pregnancies four times that of the mortality in single births The case, therefore, recorded in the present issue of THE LANCET, at p 397, by Mr GEORGE BATE, is one of much interest, since the children, three girls, were alive and well one year after birth. The fact that more boys than girls are born in the population as a whole appears to hold good in the case of triplets The figures given by RUPPIN show that the commonest combination of sexes is two boys and one girl, then one boy and two girls, then three boys, and, lastly, three girls According to him the relative proportion of the two sexes in this variety of multiple pregnancies is 104 boys to every 96 girls The interdependence that exists between general prolificacy and multiple births is shown by the statistics of the two conditions In France, for example, where the general prolificacy is low, twin pregnancies occur about once in every 92 births, as compared with a general frequency of about once in every 80 births, according to HELLIN He finds that the frequency of multiple births varies not only in different countries but in different districts in the same country The formula he gives is a convenient one for estimating roughly the frequency of the occurrence of multiple births. If twins be taken as occurring about once in every 80 births, then 80^2, or 1 in 6400 represents the frequency of the occurrence of triplets, 80^3, or 1 in 512,000, that of quadruplets, and 80^4, or 1 in 40,960,000, that of quintuplets

The Treatment of Congenital Dislocation of the Hip

THE mind of the public has recently, with the assistance of the daily press, been much exercised about the manipulative achievements of Professor LORENZ Knowing nothing of the nature of congenital luxation of the hip the lay mind is ready to look upon the LORENZ method as a revelation—as the invention of a novel form of "bloodless" surgery destined to replace ordinary methods We hear of hospitals being founded where bloodless surgery is to be practised and where no cutting instrument is ever to be used. It is difficult to say with whom these erroneous ideas originate, probably in the daily press zeal has outrun knowledge and it is with a good intention that "the new method" has been boomed. For the due consideration of the best treatment of congenital dislocation of the hip it is essential to understand the etiology and pathology In the vast majority of the cases of congenital dislocation of the hip joint the two bony surfaces which should enter into the joint are misshapen. This is *in part due to an arrest* of development and in part to an absence of the mutual moulding action between the head of the femur and the acetabulum. As a result the two bony surfaces do not fit and it is impossible in many cases to replace the head of the

Idiopathic Pernicious Anæmia

THERE are few subjects in medicine more interesting and perhaps more intricate than that which has been so exhaustively investigated by Dr WILLIAM HUNTER whose latest words upon it appear elsewhere in these columns We are sure that they will receive the attention invariably paid to the original investigator, especially when, as in this instance, his work tends to throw much light upon obscure places Nor does he speak in uncertain tones He has arrived at very definite and clear conclusions as to the real nature of pernicious anæmia, conclusions which may not after all be found to be so much at variance with the work of others as he appears to think. For we may at the outset venture to remark that in all that has been written upon this subject during the past 30 years, in that vast superstructure which Dr HUNTER ingeniously exhibits as being built over BIERMER'S foundation, there has always been in the background a class of cases which have defied attempts to assign to them a definite etiology—cases, doubtless, of the kind which ADDISON had in mind in the memorable passage of his writings Nor would it be extravagant to assert that since ADDISON'S day the advance of knowledge has shown that these so-called "idiopathic" forms of anæmia are far more limited than he surmised and that BIERMER and all who followed him have done great service in demonstrating the conditions that may contribute to induce a progressive and often fatal form of anæmia. Nevertheless, there have remained untouched the bold outlines of the simple word picture penned by the Guy's Hospital physician which mark off from a host of allied states a distinct and peculiar form of disease of the blood Dr HUNTER has therefore done well to recall to mind the salient point of ADDISON'S observation that such a disease does exist of which the main characteristic is a severe and progressively increasing anæmia "without discoverable cause"

We must refer our readers to the text of Dr HUNTER'S paper for his close and searching criticism of recent literature on pernicious anæmia, merely remarking that the criticism appears to us to be sound Indeed, from the standpoint assumed by the critic—a conviction that the condition described by ADDISON is that of a disease *sui generis*, as specific as any other specific affection—there is little room for any other kind of appreciation of these writings It is obvious that the 'pernicious anæmia' of BIERMER and the "pernicious anæmia" of every subsequent author—Dr HUNTER alone excepted—embrace much more than a single pathological or nosological entity, and we believe that this was pointed out in this country more than 20 years ago The great advance made mainly by Dr HUNTER'S investigations has been in the direction of revealing the true nature of ADDISON'S "idiopathic" affection By his researches on hæmolysis and his observations on the clinical and pathological characters of this form of pernicious anæmia Dr HUNTER has given an explanation of the disease which is thoroughly in accord with modern scientific hæmatology

So far we have taken it for granted that those who have followed BIERMER'S lead in the attempt to unravel the causes of pernicious anæmia must of necessity have dealt with many conditions which would not be regarded by Dr HUNTER as strictly falling under that category It might, however, be objected that this is not true, and that, as a matter of fact, all these observers have overlooked the essential nature of the affection which they described Happily, we are saved from so bewildering a conclusion by the scheme drawn up by Dr HUNTER who keeps ADDISON'S idiopathic anæmia carefully apart and who declares that this, the real form of pernicious anæmia, bears the impress of distinctive characters. We gather now that these differences are less clinical than pathological and above all etiological. The specific affection is "idiopathic" (Addison) or rather "hæmolytic" (Hunter), whilst all other cases which conform clinically to the type of a pernicious anæmia constitute a motley congeries of conditions all tending to the same end of impoverishment of the blood The causes which operate to bring about such a state are multifarious, ranging from insanitary surroundings to intestinal parasites, from gastro-intestinal defects to nervous shock, from insufficient and improper diet to toxic and septic agencies. The old question is always recurring and that is, Why is it that exposure to such influences and agencies should in one subject lead to a fatal and pernicious disorder of the blood and in another to comparatively slight derangement? Is there another factor at work, and, if so, of what nature is it? Hence some acute observers have been forced to believe in the existence of an underlying predisposition—never a satisfactory solution to etiological problems.

It is a singular position to which Dr HUNTER has led us and we hope that his clear and decided views will be carefully considered He has brought us back to ADDISON'S description of the disease only to demolish its essential feature—namely, its idiopathic character, but of this certainly no one will complain In the ruins of the vast superstructure which etiologists have erected over BIERMER'S work this specific disorder is not to be found. The idiopathic disease is no more idiopathic than is typhoid fever It is a definite entity, specific, infective, hæmolytic, presenting characteristic local lesions (especially a peculiar form of glossitis) and "connected in all cases with an exposure to drain poison." It only remains to discover its special bacillus and the triumph of the Addison Hunter anæmia over the Biermer Ehrlich anæmia will be assured. For the latter, according to Dr HUNTER, is no entity, it is a mass of etiological rubble which has been heaped together by the ingenuity of many minds vainly seeking for causes which, on scrutiny, prove to be inadequate to explain every case. There is no gainsaying the advantage of arriving at so definite, if humiliating, a conclusion, and we must hasten to recast our nosology accordingly For the practical outcome of such considerations is the total reversal of the situation as it was when BIERMER wrote. It

Order called Johannites from St. John the Almoner. Other people called them Hospitalarii because they served in the hospital, but, according to Felix Faber they did not take St. John the Baptist as their patron until they established themselves in Rhodes. So far Felix Faber. After the taking of Jerusalem in 1187 the Order of St. John was allowed by the courtesy of Saladin to stay in its hospital and convent for the space of one year. The next resting place of the Order was Acre. Thence, when the whole of Palestine fell into Moslem hands they moved to Cyprus and from there to Rhodes. Again being driven out in 1523 by the Moslems they went to Malta and here the Order reached at once its highest pitch of glory and its lowest ebb of dis honour, for in 1798 the remnant of the Order treacherously surrendered the island to Napoleon. The English 'langue" was free from any share in this shame owing to the Order in England having been in abeyance since the robbery of the religious houses by Henry VIII. The Order was established in England early in the twelfth century, the first house being in Clerkenwell and priories were also founded in both Ireland and Scotland. The English 'langue" was, however, formally revived in 1827 and after some vicissitudes received a Royal charter in 1880. The headquarters of the Order are again at St. John's Gate in Clerkenwell and the care of the sick in hospital is still carried on by the Order at the Ophthalmic Hospital in Jerusalem, while ambulance work, both in civil and military life together with the providing of nourishing meals for convalescents discharged from hospital, also forms part of its labours. All members of the Order and many who are not members will find both pleasure and profit in reading the history to which we have referred in these lines.

THE GERMAN WOUNDED DURING ADMIRAL SEYMOUR'S EXPEDITION

A REPORT by Staff Surgeon Major Schlick, who was in medical charge of the German detachment which accompanied Admiral Seymour in his expedition towards Peking in June, 1900 is exhaustively reviewed by Dr. Gros in the *Archives de Médecine Navale* for January. 79 men of the detachment sustained gunshot wounds and one man received a sabre cut. In eight instances the head was the seat of injury, in five the neck in eight the chest, in two the abdomen, in one the back in two the pelvis in 18 the upper extremities, and in 36 the lower extremities. Half of the gunshot wounds were caused by old fashioned weapons of large calibre, the remainder being due to small bore rifles of modern make. Only a small percentage of the wounds was inflicted at short range the distance for the most part exceeding 1000 yards. At long ranges the orifice of entrance was small and that of exit only slightly larger the track between the two running directly as though it had been produced by a stabbing instrument. In several instances long range missiles of small calibre were found imbedded either in a soft part or in a bone and wherever a fracture was noted the bone was invariably splintered. Three cases of penetrating wound of the cranium were followed by immediate death, the orifices of entrance and exit being both small, while the track between exhibited no appreciable traces of explosive action. Wounds of the face were benign and the same could be said of those that penetrated the thorax. In all the wounds of the neck, however, the prognosis was most unfavourable. In each of the two abdominal cases the liver was pierced but no reaction occurred and the patients recovered with astonishing rapidity. Surgeon Major Schlick has a great deal to say regarding the behaviour of his patients after they received their wounds. In scarcely any two of them was the general mode of reception the same. Sometimes it was a flow of blood which furnished the man with the first intimation that he had been hit. Others said they felt as if some person had struck them with a stick. In a few instances the phenomena of extreme nervous excitation made their appearance. "In such wounds," says Surgeon Major Schlick, "it is very difficult to determine how much is due to shock or to injury of the spinal cord and its membranes, or to intra medullary hæmorrhage, or to commotion of the organ." Amongst the wounded there were those who had sustained injuries of the thorax but exhibited the signs of paralysis affecting the lower limbs which lasted several hours, and also others who acted "like hysterical females," at one moment laughing and the next crying. In most these phenomena disappeared after a few hours but in a few they persisted for six or eight days. The proper treatment of these 80 wounded men was rendered very difficult by the lack of necessaries. Dressing material, antiseptics, transport, suitable food, all the essentials of modern surgery, were either insufficient or else absolutely wanting. Three operations only were performed, their urgency being imperative—namely, one amputation and two extractions of projectiles which by their situation were causing intolerable agony. In general the treatment was expectant—occlusion of orifices by sublimated pads but without washing. The officers' shirts and mosquito curtains had to be utilised as dressing material. Split bamboos served for splints as well as in some cases the telegraph wires which had been cut by the Boxers. And yet in spite of all drawbacks the results were not unfavourable. In addition to the four men who were killed on the spot four more of the wounded succumbed through internal hæmorrhage. All the rest did well.

TYPHOID FEVER OR PUERPERAL SEPSIS?

PYREXIA in the puerperium may give rise to the problem of differential diagnosis between typhoid fever and septicæmia which sometimes presents difficulty. The *Boston Medical and Surgical Journal* of Dec. 18th, 1902, contains two interesting papers on typhoid fever in the puerperium. Dr. H. T. Swain points out that while typhoid fever in the puerperium is not very rare, cases such as the following one, in which the onset is so sudden as to simulate sepsis, have been seldom recorded. A woman was admitted to the Boston Lying in Hospital in her third labour. She noticed no symptoms different from those of her previous pregnancies. She had an easy labour in the early morning. In the evening the temperature rose to 101·5° F., but the pulse rate was not elevated. Next morning the temperature was 102·5° and the pulse was 100, in the evening the temperature was 104·2° and the pulse was 130. During the day diarrhœa with 'pea soup' stools began. There was slight delirium and the tongue was coated in the centre and red at the edges. There was some abdominal distension, with general tenderness. The lochia and milk were scanty. It was difficult to determine the character of the lochia because of the continual diarrhœa and the fæcal odour about the patient. Inspection of the vagina and cervix revealed nothing abnormal. There was a macular eruption which appeared and disappeared without apparent cause. On the third day the symptoms persisted and the Widal and diazo reactions were negative. The leucocytes were 3400 per cubic millimetre. On the fourth day rose spots appeared in abundance and the spleen was felt. On the fifth day the Widal reaction could not be obtained, but the diazo reaction was present. On the tenth day the Widal reaction was still negative. It was not again sought for. At the end of a month the patient was discharged well. The sudden rise of temperature and of pulse rate without prodromata resembled sepsis rather than typhoid fever. The scanty secretion of milk was useless in differential diagnosis, because it would result from any febrile state. As to the lochia, they may be unchanged in quality and quantity in sepsis. The general abdominal femur in the acetabulum since there is no acetabulum to receive it, or so small and ill developed a cavity that it is impossible to retain the head in position even when it has been replaced. For the relief of this serious deformity three methods of treatment have been devised. Mere hip-belts can hardly be considered curative, though by limiting the mobility of the head of the femur they do tend to improve the gait The first attempts which aimed at being really curative were made by the elder PRAVAZ, he was followed by BUCKMINSTER BROWN Their methods were not essentially different and consisted in extension, lasting many months, applied to the affected limb, and, later, passive movements were carried out. The results were hardly commensurate with the time and the assiduous attention required by the method and at the present time it is almost entirely disused The next phase in the treatment was the adoption of an "open" method, the hip joint is cut down upon, the acetabulum is deepened, restraining muscles and ligaments are divided, the head is replaced, and the limb is fixed by a plaster of Paris splint In some cases the misshapen head of the femur is pared down until it fits more neatly into the acetabulum This method was introduced by HOFFA and modified by LORENZ, and in suitable cases gives fair results. The dangers from sepsis and hæmorrhage are by no means negligible. A third method yet remains, this is the "bloodless" method of forcible reposition. It was originally introduced by PACI but it has been modified by LORENZ who has abandoned his "open" operation It consists in forcibly breaking down the pelvic attachments of the muscles, especially the adductors, which resist the replacement of the head. Then by forcible abduction of the thigh the head of the femur is brought down into the position of the acetabulum. In its passage downwards the head may sometimes be felt and heard to pass over a ridge which probably represents the upper and hinder rim of the acetabulum. This is the sound of "the bone returning into its socket" which has much impressed the popular mind. To retain the head at the acetabulum the limb is fixed by plaster of Paris in a position of extreme abduction, and the plaster splint is retained for six months During this time the pressure of the head of the femur may tend to some extent to hollow out the acetabulum by causing absorption, but it is very doubtful if the action is great. After the plaster splint is removed the extreme abduction slowly disappears, without, it is said, any reproduction of the dislocation It would be premature to express at present any decided opinion as to the ultimate results of the method, especially as it has not yet been performed in this country sufficiently frequently to provide material for an opinion, but we are at least justified in saying that it cannot claim to be applicable to all forms of congenital hip dislocation, for in some cases no trace of an acetabulum can be found It is true that the risks of sepsis and hæmorrhage are removed by this operation, but the tissues around the joint are violently lacerated. Some of the credit of the method should be given to PACI who first devised it, but LORENZ has applied it to so many cases—in all, it is said, more than a thousand—that his name will certainly be associated with it. A judicious hesitancy should characterise the surgical mind until we have more certain data on which to found an opinion.

Annotations.

"Ne quid nimis."

THE ILLNESS OF THE KING

WE are authorised to make the following statement with regard to the illness of His Majesty the King For about a week past His Majesty has not been feeling in his usual health and on Friday, Jan. 30th, he complained of feeling the cold more than usual. On Monday, Feb 2nd, it was found advisable to postpone the journey to Chatsworth and on Tuesday, Feb 3rd, it became evident that His Majesty was suffering from a mild attack of influenza. The attack is but slight and the King is not confined to bed, but only to his room. Care, of course, is necessary, since influenza predisposes a patient to the attack of other infectious diseases, but so far there is no cause for anxiety There have been several cases of influenza among the members of the household

THE HOSPITALLERS OF ST JOHN OF JERUSALEM [1]

ST JOHN'S GATE in Clerkenwell is known, we daresay, to few Londoners, but most persons are acquainted by sight at any rate, with the members of the St. John Ambulance Corps who are always much to the fore on occasions when great crowds gather together in the metropolis Few, however, connect these ambulance workers with a military religious order who fought to preserve the holy places from contamination by the followers of Mahomet, but the Rev W K. R Bedford and Lieutenant Colonel Holbeche, respectively the genealogist and librarian of the Order in England have together compiled a most interesting history of the rise, fall, and resuscitation of this great Order They refer to the foundation of a hospitium for pilgrims by some merchants of Amalfi, but they do not give the circumstances surrounding the foundation. According to that exceedingly interesting book, the Evagatorium [2] of Felix Faber, the foundation occurred in the reign of Charlemagne At this time some merchants from Apulia brought some wares to the East previously quite unknown there These wares were hazel nuts (*avellanæ*) Some of these nuts came into the hands of the King of Egypt who at that time also ruled over Arabia, Palestine, and Judea, and this monarch was so delighted with the nuts that he granted a boon to the merchants of whatever they liked to ask Therefore, being charitable and pious men, they obtained leave to found a rest-house for Latin pilgrims in Jerusalem. As years went on the multitude of pilgrims increased and another hospitium was founded and dedicated to St. John the Almoner who was formerly Patriach of Alexandria, and the pilgrims were looked after by both monks and nuns who were Benedictines, but as yet there was no definite Order of Hospitallers. In the reign of the third Latin King of Jerusalem, Baldwin by name, such a multitude of pilgrims came to the city that the abbot and the abbess of the monastery and the convent respectively appointed two lay people to look after the pilgrims. One was a nobleman named Gerhard and the other was a noble Roman lady These two people were the first to assume the black mantle with the white cross and they were soon joined by others, so that in the year 1118 they were constituted into a regular der called Johannites from St John the Almoner. Others ople called them Hospitalarii because they served in the spital, but, according to Felix Faber, they did not take John the Baptist as their patron until they established emselves in Rhodes. So far Felix Faber. After the king of Jerusalem in 1187 the Order of St. John was lowed by the courtesy of Saladin to stay in its hospital d convent for the space of one year. The next resting ace of the Order was Acre. Thence when the whole of lestine fell into Moslem hands they moved to Cyprus and om there to Rhodes. Again being driven out in 1523 by the oslems they went to Malta and here the Order reached at ce its highest pitch of glory and its lowest ebb of dis nour, for in 1798 the remnant of the Order treacherously rrendered the island to Napoleon. The English "langue" is free from any share in this shame owing to e Order in England having been in abeyance since e robbery of the religious houses by Henry VIII. e Order was established in England early in the twelfth ntury, the first house being in Clerkenwell, and priories re also founded in both Ireland and Scotland. The glish "langue" was, however, formally revived in 1827 d after some vicissitudes received a Royal charter in 1888. he headquarters of the Order are again at St. John's Gate, Clerkenwell, and the care of the sick in hospital is still rried on by the Order at the Ophthalmic Hospital in rusalem, while ambulance work, both in civil and military fe, together with the providing of nourishing meals for nvalescents discharged from hospital, also forms part of its bours. All members of the Order and many who are t members will find both pleasure and profit in reading e history to which we have referred in these lines.

THE GERMAN WOUNDED DURING ADMIRAL SEYMOUR'S EXPEDITION

A REPORT by Staff Surgeon-Major Schlick, who was in edical charge of the German detachment which accom-anied Admiral Seymour in his expedition towards Peking June, 1900, is exhaustively reviewed by Dr Gros in e *Archives de Médecine Navale* for January. 79 men of the tachment sustained gunshot wounds and one man received sabre cut. In eight instances the head was the seat of jury, in five the neck, in eight the chest, in two the domen, in one the back, in two the pelvis, in 18 the upper tremities, and in 36 the lower extremities. Half of the unshot wounds were caused by old-fashioned weapons f large calibre, the remainder being due to small-bore fles of modern make. Only a small percentage of the ounds was inflicted at short range, the distance for e most part exceeding 1000 yards. At long ranges e orifice of entrance was small and that of exit only ightly larger, the track between the two running rectly as though it had been produced by a stabbing in-trument. In several instances long-range missiles of small alibre were found imbedded either in a soft part or in a one, and wherever a fracture was noted the bone was in-ariably splintered. Three cases of penetrating wound of he cranium were followed by immediate death, the orifices of ntrance and exit being both small, while the track between xhibited no appreciable traces of explosive action. Wounds f the face were benign and the same could be said of those hat penetrated the thorax. In all the wounds of the neck, owever, the prognosis was most unfavourable. In each of he two abdominal cases the liver was pierced but no reaction ccurred and the patients recovered with astonishing rapidity. urgeon-Major Schlick has a great deal to say regarding the ehaviour of his patients after they received their wounds. n scarcely any two of them was the general mode of erception the same. Sometimes it was a flow of blood which furnished the man with the first intimation that he had been hit. Others said they felt as if some person had struck them with a stick. In a few instances the phenomena of extreme nervous excitation made their appearance. "In such wounds," says Surgeon-Major Schlick, "it is very difficult to determine how much is due to shock or to injury of the spinal cord and its membranes, or to intramedullary hæmorrhage, or to commotion of the organ." Amongst the wounded there were those who had sustained injuries of the thorax but exhibited the signs of paralysis affecting the lower limbs which lasted several hours, and also others who acted "like hysterical females," at one moment laughing and the next crying. In most these phenomena disappeared after a few hours, but in a few they persisted for six or eight days. The proper treatment of these 80 wounded men was rendered very difficult by the lack of necessaries. Dressing material, antiseptics, transport, suitable food, all the essentials of modern surgery, were either insufficient or else absolutely wanting. Three operations only were performed, their urgency being imperative—namely, one amputation and two extractions of projectiles which by their situation were causing intolerable agony. In general the treatment was expectant—occlusion of orifices by sublimated pads but without washing. The officers' shirts and mosquito curtains had to be utilised as dressing material. Split bamboos served for splints as well as in some cases the telegraph wires which had been cut by the Boxers. And yet in spite of all drawbacks the results were not unfavourable. In addition to the four men who were killed on the spot four more of the wounded succumbed through internal hæmorrhage. All the rest did well.

TYPHOID FEVER OR PUERPERAL SEPSIS?

PYREXIA in the puerperium may give rise to the problem of differential diagnosis between typhoid fever and septicæmia which sometimes presents difficulty. The *Boston Medical and Surgical Journal* of Dec. 18th, 1902, contains two interesting papers on typhoid fever in the puerperium. Dr. H. T. Swain points out that while typhoid fever in the puerperium is not very rare, cases such as the following one, in which the onset is so sudden as to simulate sepsis, have been seldom recorded. A woman was admitted to the Boston Lying-in Hospital in her third labour. She noticed no symptoms different from those of her previous pregnancies. She had an easy labour in the early morning. In the evening the temperature rose to 101·5° F., but the pulse-rate was not elevated. Next morning the temperature was 102·5° and the pulse was 100; in the evening the temperature was 104·2° and the pulse was 120. During the day diarrhœa with "pea-soup" stools began. There was slight delirium and the tongue was coated in the centre and red at the edges. There was some abdominal distension, with general tenderness. The lochia and milk were scanty. It was difficult to determine the character of the lochia because of the continual diarrhœa and the fæcal odour about the patient. Inspection of the vagina and cervix revealed nothing abnormal. There was a macular eruption which appeared and disappeared without apparent cause. On the third day the symptoms persisted and the Widal and diazo reactions were negative. The leucocytes were 8400 per cubic millimetre. On the fourth day rose spots appeared in abundance and the spleen was felt. On the fifth day the Widal reaction could not be obtained, but the diazo reaction was present. On the tenth day the Widal reaction was still negative. It was not again sought for. At the end of a month the patient was discharged well. The sudden rise of temperature and of pulse-rate without prodromata resembled sepsis rather than typhoid fever. The scanty secretion of milk was useless in differential diagnosis, because it would result from any febrile state. As to the lochia, they may be unchanged in quality and quantity in sepsis. The general abdominal distension with slight tenderness might occur in either sepsis or typhoid fever Pelvic tenderness may be absent and the spleen may be enlarged in puerperal sepsis The diagnostic points in favour of typhoid fever were the low leucocyte count and the rose spots. The following case is recorded by Dr E. P Stickney A primipara was confined on Sept. 7th. Convalescence was uneventful except that urine could not be passed in the recumbent posture and catheterisation was necessary On the 22nd the patient was permitted to sit up After a hearty dinner she complained of dull pain in the cæcal region and frontal headache. The temperature was 101° F, the tongue was slightly coated, and there was tenderness over the cæcum and right ovary Next day the temperature was 101 7° and the pulse was 90 The uterus was of normal size for the period of the puerperium and there was practically no discharge On the 25th, after a restless night, during which there had been a chill, the temperature was 104 9° the headache was severe, the cheeks were flushed, and the pain and tenderness in the right iliac region were increased. The spleen could not be felt but the upper limit of dulness was at the eighth rib The blood gave the Widal reaction. On the 26th there were five loose brownish yellow motions of foul odour On the 28th rose spots appeared. Recovery ensued.

SIR GEORGE GABRIEL STOKES

DURING the past week the announcement has been made of the deaths of no less than three well known men of learning, by which great gaps have been created at the Universities of Cambridge and Oxford while the worlds of literature and of science have sustained great losses Mathematics loses an ardent student and instructor in the death of the Rev Norman Macleod Ferrers, D D, F R.S, who died at the Master's Lodge of Gonville and Caius College, Cambridge, on Jan. 31st, while literature will miss a great contributor in the person of the Rev John Earle, Professor of Anglo-Saxon in the University of Oxford. The death of Sir George Gabriel Stokes, however, which occurred on Feb 1st, removes from amongst us perhaps our most eminent mathematician and one of our most distinguished men of science Sir George Stokes was an example of a scholar who, in spite of his mathematical bias yet showed practical attainment. There is not a book on physics which has not scattered through its pages abundant references to Sir George Stokes and his work in the domain of physical science It seems to be the irony of things that he should have died (although, it must be admitted, at a ripe age) just at a time when we have been brought face to face with a new set of phenomena of which his own researches had indicated the existence His practical investigations into the nature of fluorescence are well known He showed, for example, that the fluorescence of a solution of sulphate of quinine was due to the extreme violet rays of the spectrum and to invisible rays of still higher refrangibility Thus by means of such a solution the absence of rays beyond the visible part of the spectrum was made manifest, for if the spectrum is thrown on to a screen damped with this solution fluorescence is produced beyond the usual visible part Sir George Stokes explained this phenomenon by stating that the ethereal vibrations are absorbed by the fluorescent matter which is set in vibration, the period of its vibration being usually longer, and never shorter, than the period of vibration of the ether Phosphorescence is a similar phenomenon except that it lasts for hours after the stimulating radiation is removed, whereas fluorescence is maintained only for a short while after the light ceases to fall on the substance Radiations of this kind have during recent years much perplexed the scientific world and a new property of matter known as radio activity is being studied with encouraging results, a line of study suggested by Sir George Stokes's work and the researches of Becquerel Sir George Stokes also described a number of very important experiments in regard to the phenomenon of interference and diffraction and investigated the nature of double refraction and polarised light. Probably no philosopher has done more towards unravelling the mystery of ether than has Sir George Stokes. His explanations of those phenomena depending upon the existence of the ether are marked by their lucidity and in many instances he has rendered the theory of ether tenable and consistent with well known facts He was elected a member of the Royal Society in 1851 when he was 32 years of age and a year afterwards he was awarded the Rumford medal in recognition of his valuable contributions on the nature of light In 1885 he was appointed President of the Royal Society, a position from which he retired in 1890, after being created a baronet in the previous year He had been one of the representatives in Parliament of the University of Cambridge, as was his predecessor Sir Isaac Newton. His devotion to scientific work and the results to which it has led promise to culminate in revelations not less in importance than those following the famous discovery of the laws of gravitation.

THE MEANING OF URIC ACID AND THE URATES

THE etiology of gout has always proved a fruitful source of controversy Although numerous suggestions have been advanced as to the precise nature of the disturbance in metabolism in this disease no definite decision has yet been reached Most authorities have been of opinion that there is probably defective oxidation of food stuffs, combined with imperfect elimination of the waste products of the body Uric acid and the urates have always held an important position in the pathology of the malady, though authorities differ as to the exact rôle played by those bodies. The article by Dr Woods Hutchinson which was published in THE LANCET of Jan 31st, p 288, under the title "The Meaning of Uric Acid and the Urates" not only possesses the charm of originality but the arguments upon which it is based appear to us well worthy of serious contemplation He maintains that there is no connexion whatever between the production of urea and of uric acid The uric acid produced in health comes exclusively from two sources—the larger moiety, or exogenous uric acid of Chittenden, from the nucleins and purin bases of the food, the smaller, or endogenous moiety, from the destructive metabolism of the nucleins of the body tissues Dr Woods Hutchinson maintains that it is the endogenous moiety alone which is increased in gout and lithæmia Further, he says gout and lithæmia are mere symptoms, names for a miscellaneous group of chronic toxæmic processes of widely varied origin, characterised by the production of uric acid and the urates. As most of the toxins which set up this destructive metabolism and consequent uric acid production are of intestinal origin or entry the diet prescribed in gout should be regulated solely with regard to the diminution of intestinal fermentation and putrefaction, hence the animal or nitrogenous foods need not be strictly limited or interdicted in gout, but as these foods, from their much more appetising and attractive flavours, are more likely to be taken in excess of the oxidative powers of the body some caution must be exercised so that the patient does not take undue advantage of the privileges as to diet which are allowed him. A still more emphatic statement is to the effect that as uric acid and the alloxur groups are not toxic or at best feebly so, and are not the cause of gout, the prohibition of even foods rich in nucleins and purin bases—such as red meats, roe, and sweetbreads—is declared ave no rational basis and to be clinically or doubtful ty except by diminishing the attractiveness of the ary There is much in Dr Woods Hutchinson's article thy of study, although there is no doubt his views are trary to some of those upheld by leading English and ign authorities

THE DISTRIBUTION OF PLAGUE

s regards the Mauritius a telegram from the Governor eived at the Colonial Office on Jan 30th, states that for week ending Jan. 29th there were 5 deaths from plague regards Cape Colony the medical officer of health of Colony states that no case of plague has been discovered ny place in the colony during the week ending Jan. 10th cases remained under treatment at the Plague Hos il, Port Elizabeth, at the end of the week, the last having n discovered there on Dec. 30th, 1902.

THE FALLING BIRTH-RATE IN FRANCE

n view of the *steady decrease* in the yearly numerical an of births in France, which has fallen from 932,000 in period 1881–86 to 884 000 in the period 1886–91, and to ,000 in the period 1891–96 the article by M Pinard l M. Richet in the January number of the *Annales Gynécologie et d'Obstétrique* upon the Pathological uses of the Diminution of the Birth rate in France is much interest. In presenting the results of their estigations they show very clearly that a fall in the rriage-rate cannot be accounted as the cause. The rcentage of the marriage-rate is practically the same France as it is in *England*—*viz*, 7 5 per cent. as comred with 7 4 per cent. As a matter of fact the number marriages has risen from 282,079 in 1881 *to* 295,752 in 99 The first point which the writers set themselves to termine was as to how far the lessened birth rate was due unavoidable causes and how far it was due to avoidable uses To answer this question they proceeded to estimate e percentages of sterile marriages amongst French people compared with that of other countries If it could be own that the percentage rate of sterility due to what ay be termed unavoidable causes was the same in France as other countries then it *followed* that such sterility could t afford a complete explanation of the falling birth rate cording to Matthews Duncan and Simpson the number sterile marriages in England was about 13 4 per 100. As eir results, however were based upon a *comparatively* all series of figures it was probable that the rate was ther too high. From a consideration of the French statistics ailable for the year 1896 the result was arrived at that nongst 2,027 739 marriages there were 233,369 in which ter a duration of from 15 to 24 years there were no ildren or a percentage of 11 5. It must be noted *however*, that no account was taken in these figures of children ho had died. To correct this source of error *no* French atistics were available but from a study of those of Brazil iven by M. Bertillon the writers found the *proportion* of hildless marriages lasting from 15 to 24 years in which hildren had been born but had died to be about 2 per ent. Deducting this number from the percentage already iven—viz. 11 5—gives a percentage of 9 5 childless arriages amongst those which had lasted from 15 to 4 years A more correct *comparison* could be obtained etween the statistics of Berlin and Rio de Janeiro nd those of Paris since they concerned an *urban* population alone and not a mixed urban and rural population. Amongst marriages which had lasted for the time already onsidered—viz., 15 to 24 years—there were in Berlin 12 8 per cent. in Rio de Janeiro 11 3 per cent., and in Paris 11 3 per cent without any children The differences were inconsiderable and did not explain the marked difference between the birth rate of 29 per 100 of Berlin and that of 23 per 100 of Paris The conclusion might therefore safely be drawn that the rate of sterility due to what may be termed unavoidable causes was practically the same in Paris as in other large towns Unfortunately, although they might accept the rate of sterility—viz. about 11 per cent.—as fairly correct they were quite unable to arrive at any approximate estimate of the frequency of the commoner causes of sterility As M. Pinard and M. Richet pointed out no doubt *the commonest* cause was one or *other of the forms of* venereal disease, particularly gonorrhœa. More especially *was this the case with the latter affection*, because even when apparently cured it yet frequently entailed sequelæ which produce *sterility* either in the *male or female* If we are to accept the above deductions as correct—and there can be no doubt that they are approximately true —then we are driven to the conclusion that the falling birth-rate in France is not due to an increasing degree of sterility amongst French men or women. It is due, as the writers are compelled to admit to the determination of French parents amongst almost all classes of the community not to have more than a certain number of children, and until the time comes when this determination can be altered the birth rate of France is likely to continue to fall

MEDICO-PSYCHOLOGICAL ASSOCIATION

THE next general meeting of the Medico-Psychological Association of Great Britain and Ireland will take place at the County Asylum, Mickleover, Derby, on Feb 12th, under the presidency of Dr Joseph Wiglesworth of the county asylum at Rainhill, Lancashire. The educational and Parliamentary committees will meet in the forenoon, the general meeting will commence at 3 P M, and there are ten candidates for election. Mr F J Stuart will propose a motion

> That a committee be appointed to reconsider and to report on the statistics obtained by the late Tuberculosis Committee of this association.

Papers will be read on the Stereoplasm of the Nerve Elements, by Dr W Lloyd Andriezen, on the Care and Treatment *of* Persons *of* Unsound Mind in Private Houses and Nursing Homes, by Dr. E. W White, and on Lunacy and the Law by Dr T O Wood Members are invited by Dr R J Legge to lunch at the asylum at 1 30 P M. and they will dine together at the Midland Hotel at 7 P M

THE LEUCOCYTES IN TYPHOID FEVER

ALTHOUGH from a diagnostic point of view in the examination *of* the blood in typhoid fever *the* importance of the leucocytic changes is largely overshadowed by Widal's reaction yet the former are of considerable *interest* and importance. That a condition of leucopenia or reduction in the number of the leucocytes occurs in uncomplicated cases of typhoid fever is well known, but the nature of this reduction and its variation in the course of the fever have attracted little attention in this country A careful study of these changes and of their diagnostic and prognostic import has been recorded by Dr Otto Nägeli of Zürich in the *Deutsches Archiv für Klinische Medicin* Band lxvii., S 279. He divides the course of the fever into four stages, in which the changes are as follows. In the first stage, that of the gradually rising temperature curve, there is probably a neutrophile leucocytosis of moderate degree, which soon gives place to a reduction, and at the same time the lymphocytes are diminished and the eosinophiles completely disappear or are but rarely found, in the second stage, that of continuous pyrexia, there is a further reduction of the neutrophiles and lymphocytes though towards the end *of this* stage the latter may gradually increase, in the third stage, with a remitting type of temperature, the increase of the lymphocytes becomes very distinct and a few eosinophiles begin to reappear, but the neutrophiles decrease still further, and in the fourth stage, that of declining fever, a further diminution occurs in the neutrophiles which now reach their minimum, while the lymphocytes increase to such a degree as to exceed the neutrophiles and the eosinophiles return slowly towards their normal proportion. In the first few days after the decline of the fever the restitution of the neutrophiles begins, while the lymphocytosis persists for some weeks or even months. Dr Nägeli explains these effects by supposing the action of a toxin upon the bone marrow, the preliminary increase and subsequent decrease in the number of leucocytes being due to a preliminary stimulation, followed by a subsequent depression analogous to the action of many known organic poisons on protoplasmic tissues, and definite changes are found in the bone marrow which lend support to this view. The blood conditions are of interest in relation to diagnosis, as definite changes occur before the development of Widal's reaction, while from the standpoint of prognosis Dr Nägeli finds that the presence of eosinophiles is favourable as indicating a mild infection, while the absence of lymphocyte increase is unfavourable. Most complications produce a leucocytosis.

THE MEDICAL LIFE

To the vast literature of medical addresses Mr George Munro Smith has added a welcome item in his racy presidential lecture delivered to the Bristol Medico-Chirurgical Society at the opening of its twenty-ninth session. The address is reprinted, as a small pamphlet, from the *Bristol Medico-Chirurgical Journal* for December, 1902, and its perusal provides an entertaining quarter of an hour. Mr Smith takes a wide view of medical life, its occupations, joys, sorrows, achievements, and disappointments, and their effects upon a man's character. In the manner in which this is done Mr Smith shows a sense of humour and a correct appreciation of many points in the nature and relationships of both patients and medical men. We find here no great inculcations to moral rectitude, but we have a sensible estimate of the great worth to any medical man of the conscientious performance of his various duties and of the value of a cheerful spirit and a mind open both to the lighter and to the more serious aspects of the situations in which the practitioner becomes involved. Moreover, Mr Smith gives some delightful anecdotes, one of which we would fain repeat, though it may be an old friend to many readers. The pith of it is the advice given by an eminent specialist to a lady patient to "take a saline aperient before breakfast daily and spend her morning on the downs." As a class medical men are apt to suffer from a too solely solemn view of their life. This is natural enough from the serious vicissitudes with which they mainly deal. A spice of humour, though, will alleviate their burdens and assuredly make them none the worse in practice.

THE PREVALENCE OF SMALL-POX

AT the meeting of the Poplar Borough Council held on Jan. 29th Mr F W Alexander, medical officer of health, reported that since the last meeting of the public health committee two cases of small pox had occurred and that both patients had died in circumstances that are worth the notice of our readers. The first case was that of a female, aged 27 years, of Morant-street, Poplar, where a case had occurred previously on Dec. 20th. The patient was prematurely confined of an eight months living child on Jan. 4th and was attended by a midwife. The medical officer of health, at the request of a medical practitioner, examined her on Jan 5th and found her to be suffering from small pox and too ill to be removed, and in order to prevent the spread of the disease the whole of the inmates were isolated within the house, food being supplied and the rent and medical attendance being paid at the expense of the council. The firms for whom the inmates worked were notified of the state of affairs, and various medical officers of health were informed of "contacts." The midwife was interviewed and advised about disinfection. The patient died on Jan 6th. The body was immediately placed in a coffin and removed to the mortuary, Wellington road, and the inmates of the house were taken to the shelter. The undertaker's men also went to the shelter, bathed, and had their clothes disinfected. The second patient, the prematurely born male infant of the above patient, developed small pox on Jan 10th at the council's shelter and was removed on the same day and has since died. The child was vaccinated as soon as born. The husband of the deceased woman and his mother who nursed her were detained at the shelter as they were not revaccinated immediately. The other inmates were allowed to return home as soon as the premises were disinfected. The medical officer of health commended the prompt manner in which the above measures were carried out. Such prompt action by the officers no doubt prevented the spread of disease. —The Local Government Board for Scotland intimates that during the period from Jan 16th to 31st inclusive five cases of small pox have been notified to it, four of these occurring in the burgh of Leith and the other at Prinlaws, Leslie. The Leith cases are all traced to one source—viz., a case imported from Riga.

"RETURN" CASES OF SCARLET FEVER

A CASE of considerable interest was recently tried at the Lowestoft County Court. A claim was made against the mayor, aldermen, and burgesses of the borough to recover the sum of £50 as compensation for damages sustained through the negligence of the defendants or their servants in discharging the plaintiff's daughter from the Lowestoft Isolation Hospital on August 29th last in a verminous and infectious condition. The child had been an inmate of the hospital for nine weeks and three days, suffering from scarlet fever, and the plaintiff maintained that in consequence of being discharged in the condition alleged the child infected two other children of the plaintiff with scarlet fever, whereby the plaintiff had suffered loss as represented by the amount of the claim. The case occupied five hours and amongst the witnesses was Dr O K Millard, medical officer of health of Leicester. The question had arisen as to whether lice could be instrumental in communicating scarlet fever. Dr Millard stated that he did not know of any authenticated cases in which infection had been so spread. We are not aware of any observations on this point, but it is certainly a matter of importance to know if infection can be carried by vermin. Scarlet fever can be conveyed from an infected person by means of fomites and as cutaneous particles are a source of infection it would seem quite possible that lice might carry with them from one person to another the pathogenic organisms. Dr J R O'Brien of Lowestoft was of opinion that the fever might be transmitted by insects or flies as well as by means of linen and other clothes. The judge entered judgment for the defendants for reasons which he proceeded to enumerate. His speech was a lengthy one and dealt fully with the matter. On points of law his remarks were very interesting and more or less correct. From the medical evidence he came to the conclusion that lice were not the cause of the spread of the disease, but we should prefer to consider this matter as well worthy of future investigation. The subject of "return" cases of scarlet fever is still an open one. The matter was under consideration at the last meeting of the British Medical Association. Dr Millard, who opened the discussion, regarded "return" cases as essentially a 'bor nomenon" and recommended as the most effectual means the prevention of such cases the isolation of convalescents n acute cases prior to discharge from hospital The fful supervision of cleanliness in all patients about to be harged should also be insisted upon, and under this ane would be included the freedom of the head from or other vermin

THE HUNTERIAN SOCIETY

HE annual Hunterian oration will be delivered in the idon Institution, E C, on Wednesday, Feb 11th, at) P M., by Mr T H Openshaw, C M.G The subject he oration is John Hunter His Influence on Surgery, h some Remarks on the Treatment of Appendicitis." y member of the medical profession can be present at the ivery of the oration The annual dinner of the society l take place on Friday, Feb 13th, at 7 P M. in the cadéro Restaurant

SHELL-FISH AND SEWAGE CONTAMINATION

HE question of the pollution of shell fish with sewage we are glad to see, not going to be dropped. Indeed, subject is being discussed throughout the country by all nicipal authorities and we may hope that as a result some portant step in sanitation is likely to be advanced. In a ent report presented to the sanitary committee of the corration of the City of London the medical officer of health, W Collingridge, publishes the results of a very interesting quiry into this question, while it is established beyond dis te by the experiments of Dr Klein that cockles and oysters e frequently polluted with sewage Further, there can be doubt that shell fish in general are often the origin of an tbreak of enteric fever Similarly the public health mmittee of the London County Council presented a long port upon the subject at a meeting of the Council on b 3rd, and after some discussion the recommendation the committee was adopted, "that a letter be addressed the Local Government Board expressing the Council's e that in the interests of the public health the ard will as soon as possible take steps to obtain an amend nt of the law so as to prohibit under heavy penalties the ing down of all edible forms of shell fish in sewage-luted creeks or other dangerous localities and the sale of h shell fish for human consumption, and that all un luted layings fattening beds, and storage ponds at ent in use may be protected from pollution by sewage by person or sanitary authority

THE LATE DR FEDERICO RUBIO Y GALI

r Federico Rubio y Gali of Se ille died on August 31st, at the age of 75 years, as mentioned in THE LANCET Oct. 11th, p 1023 He was one of the most eminent cons in Spain and in recognition of his great reputation high professional position he was among the dis-uished foreigners who received the honorary diploma R.C S Eng on the occasion of the centenary of the al College of Surgeons of England. Another notable nish medical man Dr Salvador Cardenal Fernandez Barcelona, received the honorary Fellowship at the e time.[1] Dr Rubio's obsequies were solemnised at lle on Dec. 6th in the presence of a great con se of sympathetic friends and amid the animated es of an impressive ceremonial. We have received a and minutely detailed account of the proceedings, for h we are indebted to a correspondent, who makes icular mention of the kind reception given to him by Dr on de la Sota y Lastra, Dean of the Seville Medical ulty, Dr Laborde, who retains pleasant memories of two years spent at Guy's Hospital, and Dr Lasso de la Vega. The company, consisting of graduates and students of Cadiz and Seville, assembled in the large academic hall of the school founded in Seville by the deceased Led by the Dean the gathering passed into the street and so into the Church of the Mother of God, which is the chapel of the medical school. The centre of this long narrow building, roofed with carved wood, was occupied by a stately catafalque four squares of black and gold terminating above in a funeral urn. On the conclusion of Divine service the company returned to the large hall where eloquent and touching addresses were delivered by Dr Laborde and Dr Lasso de la Vega

CHOREA ELECTRICA

CHOREA electrica a rare nervous disease of children, was first described by Dubini in 1849 Most of our knowledge of it, however, dates from the observations made by Henoch 20 years ago In the *Berliner Klinische Wochenschrift* of Dec 22nd, 1902 Dr Ludwig Bruns of Hanover gives an account of the main varieties of this disease based on a study of 30 cases The disease is found to occur exclusively in children of both sexes, the ages varying from nine to 15 years. The characteristic attacks consist of sudden muscular shocks or contractions limited to the neck and shoulder muscles—viz, the sterno-mastoid, levator anguli scapulæ, pectorales major and minor, and the trapezius The muscular contractions are sharp and sudden "as though induced by an electric shock"—hence the name chorea electrica. The disease, adds Dr Bruns, is not related to Sydenham's chorea. He recognises three varieties of chorea electrica —viz., chorea electrica proper, a hysterical variety, and an epileptic variety The hysterical variety of this affection is readily cured by the therapeutics ordinarily employed for hysteria. He records a case of this as exemplified in a girl, aged nine years, the child of a highly neurotic mother Separation from the mother with firm and judicious management soon cured her of the trouble The epileptic variety is very refractory to treatment, as the condition is due to a grave lesion of the cerebral hemispheres Hydrotherapy, an open air life, and a diet that is digestible and free from irritating or highly stimulating ingredients are among the general methods of treatment for the epileptic form and the same remarks apply to chorea electrica proper, which is rather more amenable to such treatment.

THE BRITISH GYNÆCOLOGICAL SOCIETY

THE Fellows of the British Gynæcological Society and their friends attended the annual dinner on Jan. 29th at the Café Monico, Piccadilly circus, London, W in large numbers. Sir John Halliday Croom, President of the Royal College of Surgeons of Edinburgh, was accorded an enthusiastic reception on taking the chair as president of the society Dr S Buckley President of the North of England Obstetrical and Gynæcological Society, in the course of his speech while giving the toast of "The British Gynæcological Society discoursed on the fame of the names that occurred in the lists of its officers The society, he said, was known throughout the gynæcological world and he described how the formation of the North of England Obstetrical and Gynæcological Society had been followed by excellent results in securing good fellowship amongst its members. Sir John Halliday Croom, in acknowledging this toast, well sustained his reputation for wit and humour The next speech was by Dr H Macnaughton Jones who was intrusted with the task of proposing the toast of Universities and Medical Corporations He deplored the disappearance of the Queen's University in Cork. He showed how many brilliant men had been trained for useful service to the State in the Queen's University, and explained how important it was to have teaching universities and not merely examining boards to test knowledge. After Mr W Parson, the Master of the Society of Apothecaries of London, had spoken in answer to the toast, Dr F F Schacht said a few words, remarking that the universities had at last turned their attention to the medical aspects of the education which they provided. In giving the toast of the "Sister Societies," Dr Heywood Smith warmly urged the foundation of a Royal Academy of Medicine. The evening concluded by the President of the Clinical Society of London, Mr Howard Marsh, acknowledging this toast in an effective and thoughtful speech

[1] THE LANCET August 4th, 1900 p. 329.

QUICK LUNCHES

PROPOSALS have recently appeared in the daily press in favour of the inauguration of a system of quick lunches by which the busy man may have a substantial midday meal served expeditiously, the partaking of which shall occupy but a few minutes We do not hesitate to ask that all our readers will impress upon their patients that the adoption of this proposal would be a wicked physiological step The repair of the body is not a process to be trifled with in this way, eating should not be done in a hurry The demands of business may be pressing, but the demands of the body are in reality more serious Just as by stoking a steam engine to cramming point the fuel burns badly and the intensity of the fire is lowered, so by bolting his food the vital processes within a man's body are hindered rather than helped Necessarily food eaten rapidly escapes in a great measure the preparatory processes of digestion and sooner or later a breakdown in the maltreated human machine supervenes In a word, hurrying over eating is fatal to the healthy sustenance of the body

LECTURES of the Royal College of Physicians of London for 1903 will be delivered at the College, Pall Mall East, on each of the following Tuesdays and Thursdays at 5 o'clock. Milroy Lectures The Causes, Prevalence, and Control of Tuberculosis, by Dr H T Bulstrode, on March 5th, 10th, and 12th Goulstonian Lectures Theories of Immunity and their Clinical Application, by Dr A. S F Grünbaum, on March 17th, 19th, and 24th Lumleian Lectures On Infective Endocarditis mainly in its Clinical Aspects by Dr T R. Glynn, on March 26th, 31st, and April 2nd.

THE Eleventh International Congress of Hygiene and Demography will be held in Brussels from Sept 2nd to 8th under the patronage of H M the King of the Belgians The secretary general of the Congress is Professor Dr F Putzeys All information and programmes can be obtained from Dr Paul F Moline, 42, Walton street, Chelsea, London, S W, the honorary secretary of the British committee

A MEETING of the Medico Legal Society will be held on Tuesday next, Feb 10th, at 8 P M. at 20, Hanover square to continue the discussion upon Dr Littlejohn's paper on Medico Legal Post-Mortem Examinations and to hear a paper upon the Whitechapel Murders (Jack the-Ripper) Members of the profession are invited to be present

Dr C Luxmoore Drew has appointed Dr S Ingleby Oddie, barrister at-law of the Middle Temple, to be deputy coroner for the Western Division of London, vice Dr H. R. Oswald, who was recently selected as coroner for South east London.

NEW METHODS OF MEDICAL TREATMENT

A PAPER READ BY PROFESSOR BOUCHARD AT A GENERAL MEETING OF THE MEDICAL CONGRESS HELD IN CAIRO FROM DEC 19TH TO 23RD, 1902

(*Translated and abstracted specially for* THE LANCET.)

OFTEN a patient when he has recovered attributes his cure to the medical man, it is rare for a medical man, if he is well educated, to consider himself the cause of the cure. It is, however, quite exceptional that he has not been useful, he has relieved, he has helped on the acts which lead naturally to cure, he has avoided possible dangers, he has kept up the strength of the patient, and has given him the necessary time in which to get well. He is not directly responsible for the processes which heal, for these processes come about gradually during the succeeding phases of the illness. *Natura medicatrix*

Spontaneous cure is the rule, at least in acute diseases. It is not the same thing in chronic diseases, which are chronic precisely because they have no natural tendency towards cure It is just in these cases that medical assistance is necessary and that the art is shown in its dignity and power. Empiricism has given us opium, which does not often cure but which relieves almost always, and the empiricism of olden days has given us nearly all our drugs, among which are several which cure, such as quinine mercury, the iodides, arsenic, colchicum, and salicin—all drugs the use of which we have learnt by happy accident. Each of these drugs cures a special disease, and almost exclusively that disease, its action being specific Our forefathers did not know or even suspect the reason, but most of us to-day know the secret of their action. They influence the poison by means of constitutional treatment

We now know something about the causes of malaria and actinomycosis, but that of rheumatism is still under discussion, and we have neither seen nor cultivated the micro-organism of syphilis Our ancestors discovered remedies without knowing the cause of their action, but in modern days we have not discovered new specifics, though I must not forget the serums which are the new and brilliant victory of the nineteenth century

I have often thought that in both local diseases and general diseases which are localised if a general drug treatment exercises a specific cure one might confine the administration of the remedy exclusively to the diseased tissue and attempt the cure by injecting into the affected part the drug which is of known utility when it is distributed all over the body In a case of acute articular rheumatism a man weighing 135 pounds, who takes every day by the mouth 90 grains of salicylate of sodium, sees all his joint affections disappear Every day a grain of the drug has entered into every pound and a half of his body, and of course a very small proportion of this has found its way to the soft parts surrounding the affected joints. As a matter of fact, an acute articular rheumatism disappears after the injection *in situ* of extremely small quantities of salicylate of soda. I will not say that I have cured a case with one sixth of a grain, but I have seen rheumatic joints rapidly cured by half a grain, and it is exceptional if a symptom is not cleared up by from two to three grains dissolved in a drachm of water

In no case of acute rheumatism can the local treatment however satisfactory it appears to be, be considered sufficient. It is true that it reduces the temperature when only one joint is affected but it does not prevent the development of affections of other joints or the invasion of serous membranes In such cases general treatment is absolutely necessary and if it proves insufficient local treatment can be used as an aid Of course, it must be understood that I am not speaking of true rheumatism and not of infectious rheumatic conditions such as gonorrhœal rheumatism, which, however, can have its pain relieved by local salicylic treatment.

Several times an injection into the painful thoracic muscles has stopped an early pleurisy and in the case of pericarditis I have seen an injection of one and a half grains lower the fever from 102° to 100° F, then a second injection was made and in three days friction had disappeared endocarditis I have failed and cannot pretend to attain the success of Moritz Benedikt, who with a solution of carbolic acid (2 per cent) has seen cardiac affections disappear without leaving any trace behind. I have, however, cured cases of painful muscular contraction of the adductors of he thigh and I have seen good results in neuritis such as ciatica. In these cases I injected in the neighbourhood of he diseased tissues, not in the tendons or nerves. In he same way, when it is a question of inflammation of the serous linings of joints or of internal organs, I have not introduced the drug into the affected cavities, but into the neighbouring tissues as near as possible to hem.

The success which I have mentioned made me wonder if it would be possible to apply local salicylate treatment to other painful nervous affections. I tried it in tabes dorsalis but obtained no result and Professor Déjerine also met with no success. I then tried injections of iodide of potassium (3 per cent.) and these injections have permanently eased the pain in some cases of ataxy I did not inject more than 30 minims each time, being about one grain of the iodide I then resolved to join biniodide of mercury to the iodide of potassium and thus triumphed over many acute obstinate pains

These early experiments encouraged me to try the local treatment of syphilis by the same small doses of specific drugs. I have not had either the time or the opportunity to collect numerous cases as I have been able to do for rheumatism, so I will simply state what I have seen A man with an ulcerating gumma on the back had been treated by mercury and iodide and the two combined. He had also had inunctions and subcutaneous injections of mercury far from the gumma. As all this general treatment seemed *to be unavailing I stopped it and injected near the gumma* iodide of potassium. After one grain of iodide had been injected the gumma healed. In another case, after unsuccessful general treatment and its being relinquished, the gumma disappeared under the influence of three injections each of one grain of iodide of potassium A woman suffering from severe syphilis had on several parts of her body deeply ulcerating condylomata. I gave her mercury and iodide in the ordinary way, but at the end of a month her stomach could no longer take the iodide, the injections of benzoate, and later of cyanide, of mercury produced lumps of the size of a nut and her general condition was no better I therefore stopped the former treatment and experimented on some of the tumours by injecting into them iodide of potassium and biniodide of mercury In three days a condyloma into the base of which I had made two injections was cured Another ulceration was healed after six injections. During this time the other condylomata were not treated at all and showed no improvement. The patient's weakness increased and her hair again began to fall out.

With or without general *treatment* I venture to hope that local treatment will some day triumph over those painful or dangerous local manifestations which we sometimes see developing on the face, in the tongue or on the eye. One may even hope that some day deep lesions will be treated by this method. It is not of course, quite certain how these infinitesimal local doses produce their action. Local treatment, because it is local, brings the drug into the affected spot and makes it antiseptic without a general toxic diffusion in the whole body Ophthalmic surgeons whom we ought to have imitated long ago bring the drug whether it is specific or not, as near as possible to the affected part Again, local treatment of a nasal coryza often prevents a general infection of the respiratory passages, and local antisepsis of the digestive canal is used to prevent gastric fermentation and intestinal putrefaction.

It is silly and dangerous to try to cast the horoscope of this twentieth century I am certain that our successors will open new paths which we do not suspect. but I can at least say in what direction treatment is tending to-day Without neglecting general treatment local means are being more and more employed sometimes by setting up an antiseptic action, sometimes by awakening antitoxic processes, by which methods the treatment becomes a cure.

Modern treatment, above all is inspired by the ideas of infection, which are the glory of the nineteenth century and which usher in the twentieth full of the teaching and the memory of those two benefactors of all ages, Pasteur and Lister

RECENT RESEARCHES IN MALARIA

A VALUABLE contribution to our knowledge of several questions connected with malaria has recently been published in Calcutta.[1] It forms No 2 of the new series of Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India and is from the pen of Captain S P James, I.M.S, on special duty with the Royal Society's Commission on Malaria. In some of the work here recorded he was associated with Dr J W W Stephens and Dr S. R. Christophers The volume consists of 106 large pages, contains many illustrations, and is divided into seven chapters headed respectively Methods of Investigation, Observations on Anopheles Mosquitoes and their Larvæ, Malarial Infection of Native Children, Prevalence of Malaria in Different Parts of India, Enlarged Spleens and Malarial Infection, Malarial Parasites and Fevers of India, and Observations on Birds.

In his classification of Indian anopheles Captain James recognises 16 species, among which anopheles fluviatilis and anopheles culicifacies are the most common conveyers of malaria, of anopheles Rossii he says that it is almost certainly the commonest species in India and that the three species of the human malaria parasite can be made experimentally to develop in it but he has never yet found it infected in nature. Of the remaining species most are either of rare occurrence or are very seldom found in human habitations or have not been found to be infected with malaria in the natural state. It has been suggested that the naturally uninfected anopheles may bite only cattle and horses It has been discovered that the embryoes of filaria sanguinis hominis can develop in anopheles nigerrimus and anopheles Rossii. In consequence of the difficulty which is usually found in the identification of the different species of Indian anopheles Captain James recommends a classification in three primary subdivisions determined by the palp markings—namely (1) palpi unbanded, (2) palpi with four white bands, and (3) palpi with three white bands. Dr Christophers has made the important observation that anopheletes not only select their breeding places but that each species has a particular kind of breeding ground that it prefers to any other There is evidence to show that the mosquitoes which infest human habitations will readily fly to a breeding place a quarter of a mile away but that they will hardly ever fly over three quarters of a mile.

It was discovered by Professor Robert Koch and independently by Dr Stephens and Dr Christophers that a large percentage of native children in Africa constantly have malaria parasites in their blood although at the time they may present none of the more evident clinical symptoms of malarial fever Captain James has confirmed and extended these observations for certain parts of India, in some of which there is an infection of from 60 to 75 per cent of the children under ten years of age with no infection of adults. This percentage of infected children he says, affords a very true test of the endemicity of malaria and the figure representing it may be termed the "malarial endemicity index" or shortly, the "endemic index." These children are the chief source from which anopheles mosquitoes become infected. As in Africa so in certain highly malarious districts of India, there is a diminished infection of the children with advancing age and the adults are relatively immune, but in less malarious districts in India the immunity of the adult native is not so marked and the diminished infection of the children at advancing age-periods is not shown It has been said that these infected children present no clinical symptoms of malaria. Captain James remarks that this is no doubt true in the early part of the day, but in the evening many of them have to lie down, their temperatures rise, and careful examination shows that their general health is seriously affected. One of the children in whom quartan parasites were found was only nine months old. Some parts of India, such as Calcutta and the plains of Bengal, are almost free from malaria while others suffer greatly In Calcutta anopheles is abundant, numerous breeding grounds are close at hand,

---

[1] Malaria in India. By Captain S. P James I M.S Issued under the authority of the Government of India. Calcutta, 1902, pp. 106 price 2s. 3d. Obtainable from seven bookselling firms in London from Williams and Norgate, Oxford, and from Deighton Bell and Co Cambridge.

and apparently every condition is favourable to the development of malaria, and yet of 182 children examined by the Commissioners of the Royal Society of London none had either parasites in their blood or enlargement of the spleen Practically the only species of anopheles which was present in the localities where these children lived was anopheles Rossii. The mere fact that it could exist in large numbers without producing any infection in the children was in itself suggestive that the species was not a good carrier of malaria. Excluding some peculiar instances of which Calcutta is one, it may be said that there is a direct relation between the extent and nearness of breeding grounds, the abundance of anopheletes, and the amount of malaria While in Calcutta there were abundance of anopheletes Rossii and no malaria, on the other hand, in the Duars (a line of sub Himalayan valleys in north east Bengal) there were a relatively small number of anopheletes fluviatilis (of which, however, 6 25 per cent. were found to be infected with sporozoites, and a large amount of malaria. In many parts of India the seasonal variation in the amount of malaria is very marked especially in the north, where the climatic conditions undergo great changes Thus at Mian Mir in the Punjab the malaria carrying species of anopheles (anopheles culicifacies) is rare until the beginning of June, from July until the end of October the anopheletes increase very rapidly, during November they gradually decrease, and by the middle of December they have completely disappeared, not to be seen again until May Correspondingly, the "endemic index" in the Mian Mir syce lines was 56 per cent in October and 15 per cent in December

Captain James disapproves of the routine treatment of "fever" by the immediate administration of quinine He believes that if the case is really one of malaria to withhold quinine for a few days (in the absence of parasites from the peripheral circulation) will not endanger the patient in any way and if the case is not one of malaria the administration of quinine in doses suitable for a case of that disease is certainly harmful In conclusion, Captain James says that complete protection from malaria may be insured by any individual who is willing to take the trouble to pay scrupulous attention to the use of a good mosquito curtain at night and to protect himself from being bitten during the evening hours If these precautions are taken it is quite unnecessary to use quinine as a prophylactic. He had visited the most malarious parts of India without having a day's fever merely by using the mosquito-net and wearing high boots or putties in the evening By means of the same precautions, also and without taking any quinine Dr Stephens had previously passed two years in the most malarious parts of Africa without a single attack of malaria.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AN ordinary Comitia was held on Jan. 29th, Sir WILLIAM SELBY CHURCH, Bart., K C B, the President, being in the chair

The following gentlemen having passed the required examination were elected Members of the College Arthur Herbert Hayes, L R C P Lond, Goldwin William Howland, B A, M B Toronto, L R C P Lond, Frederick William Price, M B Edin, Henry Edmund Symes Thompson M A Cantab, L R C P Lond, George Lestock Thornton, M A Cantab, L R C P Lond, John Abernethy Willett, M B Oxon, L R C P Lond, and Herbert Williamson, M A, M B Cantab, L R C P Lond

Licences were granted to 94 gentlemen who had passed the necessary examinations

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England to the following gentlemen Bertram Leeds Thomas Barnett, M B, B C Cantab, L.R.C P Lond, M R C S Eng, Herbert James Barratt, L.R.C P Lond, M R C S Eng, John Bell, L R.C P Lond, M R.C S Eng, James Bennett, L R C P Lond, M R C S. Eng, Edward Collins Bousfield, L.R.C P Lond, M R.C S Eng, Edwin Harold Brown, M D Brux, M R.C P Lond, L.R.C S Edin., Richard Foster Clark, L.R C P Lond, M R.C S Eng, Alexander Gordon Davidson, M D, C M Edin, Arthur Briggs Dunne, M.B, B C Cantab, L R C P Lond M.R.C S Eng, L.S A., Ernest Gardiner Hill, L R C P Lond, M R C S Eng, Gwilym Prosser Wozencroft James, L R.C P Lond, M R.C.S Eng, William Charnett Lodwidge, L R C P Lond, M R C S Eng, Thomas Stratford Logan, L R C P & S Edin, F F P S Glasg, [illegible] Milburn, L R C P Lond, M R C S Eng, David James Morgan, M B, B C Cantab, L S A, William Murray, M B Ch B Edin, John Moir Petrie M B Ch B Aberd., and William John Shannon, M B, B Ch R U I

The PRESIDENT announced that he had nominated Dr. E F Trevelyan (Leeds) as Bradshaw Lecturer for 1903 and that the Council had nominated Dr William Williams (Cardiff) as Milroy Lecturer for 1904

The PRESIDENT also announced that the Gilbert Blane medals had been awarded to the following officers Christopher Louis White Bunton, Surgeon R N H.M.S. *Forte*, and John Falconer Hall Staff Surgeon R.N. Naval Brigade North China

The following communications were received —1 From the Clerk to the Privy Council, announcing the opening of the International Medical Congress at Madrid on April 23rd next. 2. From the Controller of His Majesty's Stationery Office, stating the terms of an agreement with the College to print and to issue a new edition of the "Nomenclature of Diseases" 3 From the Board of Trade Marine Department, in reply to the College, stating that a translation was being prepared of the report of the Norwegian Commission on Beri beri.

The following Fellows were elected Councillors —Dr D B Lees, Dr J A. Ormerod, Sir Isambard Owen, Dr Percy Kidd, and Dr T Stevenson. Dr Theodore Williams was reappointed a representative of the College on the Court of Governors of the University of Birmingham

The following motion was proposed by the Second Censor (Dr G VIVIAN POORE) and seconded by Dr J K FOWLER —

> That the President be requested to nominate a small committee to consider and report to the College as to whether or not any change be desirable in the date and arrangements for the annual Harveian festival.

The motion was carried and the PRESIDENT nominated the following Fellows as members of the committee The Treasurer (Sir Dyce Duckworth), Dr Poore, Dr Fowler, Dr T T Whipham, Dr F W Pavy, and the President.

A report was received from the representative of the College (Dr Norman Moore) in the General Medical Council on the proceedings of the Council affecting the College at the November session

The quarterly report of the College Finance Committee was received and adopted

A report was received from the committee of management dated Dec. 29th, 1902 The following recommendations were embodied in the report —

> 1 That the Rotunda Hospital Dublin be recognised as a place of instruction in midwifery and gynæcology for the certificates required by Clauses 5 (*h*) 6 (*d*) and 11 par ii. Section I of the Regulations of the Examining Board in England
>
> 2. That the University of Minnesota United States be added to the list of universities at which the curriculum of professional study required for the diplomas of the Royal Colleges may be pursued and whose graduates may be admitted to the Final Examination of the Examining Board in England on production of the required certificates of study

The report was adopted.

After some further business the PRESIDENT dissolved the Comitia.

MEDICINE AND THE LAW

The Peasenhall Case

THE man Gardiner, twice tried without result for the murder of Rose Harsent at Peasenhall on June 1st, 1902, has been set at liberty, and no one has ventured to express disapproval of the decision of the Attorney-General authorising the entry of a *nolle prosequi* against him. The two abortive trials which have taken place, each resulting in the disagreement of the jury, have called attention to the undesirable state of affairs which at times arises owing to the law requiring a unanimous verdict in order that a prisoner may be convicted. This, however, is not the only cause which has awakened the sympathy with Gardiner that has been expressed since his second trial. There appears to be no doubt that a very considerable majority of the jury who tried him were in favour of a conviction, so that he at least cannot complain of the fact that in England the verdict of ority, however large, is not sufficient. It was, how- ealised by the public after the second jury had dis- l that the crime for which he was indicted, admittedly a murder committed by somebody, had taken place in 1902, that Gardiner had been tried for the first in November and again in January, 1903 and that was to be once more sent before a Suffolk jury uld have to lie in prison for more than a year before timate decision of his fate. Writing of this case in LANCET after the first trial[1] we commented upon the is hardship involved in the long interval that would before the second hearing if it was to take place at unty assizes as then arranged. The necessity for this estioned and in the light of what has since occurred rdship appears to be even greater, although no doubt, her course than that actually pursued would have been ovation. It is clearly not right that the State should it is avoidable, increase the punishment of a criminal lict an undeserved penalty upon an innocent person lding prolonged mental torture to the anxiety and s inseparable from an accusation of serious crime. cuteness of the mental distress caused to the prisoner rial that lasts for several days and by the expectation while he lies in gaol, cannot be precisely gauged. It vary in degree according to the temperament of the n subjected to it and other circumstances, but what- the temperament may be, all will consider that the hening of the period of suspense must increase the upon the mind undergoing it and that where the life e prisoner is at issue the strain must in all cases be very . In some cases it may reach, or almost reach, the point epriving the prisoner of reason altogether It should be remembered, apart from the question of inflict- unnecessary pain, mental or otherwise, that accused ns, whether they can pay for advocacy or not, have to nd largely upon themselves for the guidance of their ice and that a man, however broken down by anxiety waiting he may be, may nowadays practically have no e but to face in the witness-box a jury eager to judge of uilt or innocence by his appearance and demeanour as as by the readiness and clearness of his replies to ination and cross-examination

is last innovation in the criminal procedure of the try made by the admission of the accused, or the and or wife of the accused, to give evidence is aps more calculated than any that preceded it to intro- a doubt into the minds of one or two jurymen which not affect the judgment of their fellows, so that what happened in the case of Gardiner may at any time occur n while the interval between his two trials is the usual rval that occurs between country assizes. In London, ever the Central Criminal Court sits practically every th and there is special provision made by statute for removal to it of cases otherwise out of its jurisdiction re it appears expedient to the ends of justice that should be so removed. The removal of a trial in ing the evidence of a number of witnesses to London the imposing of it upon a London jury is not a light ter, but it is not unheard of, and few would complain in e exceptional cases in which the object was to relieve a w-creature from needless suffering The recent case of . Penruddocke, transferred to the Central Criminal Court account of the alleged feeling against the accused in tshire, affords an instance of a trial transferred in un- al circumstances of a different kind from those which ounded the Peasenhall case, but we have not heard that nesses or jury expressed any dissatisfaction at the course en. At the same time we are not aware that delay alone ever been made the cause of such removal, although many ges and others have called attention to the long time ing which prisoners are often kept awaiting their trial. atever course, however, might have been taken with ard to Gardiner his case has shown that in this country ay may occur before the acquittal or condemnation of an used person which English laymen, at all events, have ally only associated with foreign courts of justice. It also shown that public opinion and public sympathy are ongly opposed to such delay, apart from any views that y be held with regard to the prisoner's guilt or innocence.

Flannelette and Fire

Two inquests held on the same day recently by Mr ontbeck showed that both the deaths under consideration were due to the wearing of flannelette underclothing which had caught fire. In the one case an adult, a woman, aged 60 years, was the sufferer She died in St George's Hospital. In the other the victim was a small boy aged three years and nine months, who was wearing flannelette and in the absence of his mother set himself on fire by playing with matches. He died in King's College Hospital. THE LANCET has often called attention to the inflammability of flannelette and so have the lay newspapers, chiefly in reporting deaths due to it, but whether such warnings as these reach the ears of the persons who most need them may be doubted. It might do some good if the sellers of flannelette, or of garments made of it, were compelled to deliver with each portion or article sold a printed warning as to its dangerous peculiarity

The Drink Question.

Mr J T Bottle, a justice of the peace at Great Yarmouth, has contributed an interesting letter to the *Times* upon the drink question Mr Bottle does not share the views of the Home Secretary as to the impossibility of judges and magistrates keeping records for the guidance of those interested in the public health as to the number of convictions taking place before them in which the offence is traceable to drink. Mr Bottle has himself kept a record of such convictions where he himself has sat as a magistrate, and he considers that in the last 12 years 60 per cent. of these have been due, directly or indirectly, to drink. In his letter Mr Bottle calls attention to the power that drink sellers have to diminish the evils of drunkenness by exercising care in carrying on their trade, and he illustrates this from recent experience at Great Yarmouth, a town of which he says, "The number of licensed houses is 306 with a population of 51,000 or 1 to 167, whilst the proportion of on licences is 1 to 189, a more ominous record probably than that of any other considerable town in England."

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on Feb 3rd, SIR THOMAS R. FRASER, Vice President, being in the chair

David James Galloway, M.D, M.R C P Edin., Singapore, was admitted by ballot to the Fellowship of the College.

The REGISTRAR reported that since the last quarterly meeting 37 persons had obtained the Licence of the College by examination

The Parkin prize, which is in the gift of the College, was awarded after competition to Charles James Lewis, M.D, F R C P Edin The subject of the essay on the present occasion was, in terms of the deed of bequest 'On the Curative Effects of Carbonic Acid Gas or other Forms of Carbon in Cholera, for Different Forms of Fever and other Diseases.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8880 births and 5229 deaths were registered during the week ending Jan. 31st. The annual rate of mortality in these towns, which had been 18 5 17 5, and 20 1 per 1000 in the three preceding weeks declined again last week to 18 1 per 1000 In London the death rate was 17 7 per 1000, while it averaged 18 2 in the 75 other large towns. The lowest death rates in these towns were 7 6 in West Ham, 8 2 in Handsworth, 9 2 in Devonport, 10 1 in Burton-on-Trent, 10 8 in Wolverhampton, 11 5 in Barrow in Furness, 11 6 in Wallasey and 12 0 in Swansea, the highest rates were 23 1 in Hanley 23 3 in South Shields, 23 5 in West Bromwich, 23 7 in Norwich, 24 0 in Oldham, 24 6 in Rotherham, 25 1 in Newcastle-on-Tyne, and 26 0 in Wigan The 5229 deaths in these towns last week included 493 which were referred to the principal infectious diseases against 504 450, and 539 in the three preceding weeks, of these 493 deaths 163 resulted from whooping-cough, 105 from measles, 71 from diphtheria, 60 from diarrhœa, 47 from scarlet fever, 34 from 'fever' (principally enteric), and 13 from small pox. No death from any of these diseases was registered last week in Ipswich, Wolverhampton, Handsworth, Wallasey, Bootle, York, or Stockton on Tees, while the highest death rates from these principal infectious diseases were recorded in Croydon, Hanley, Walsall, West Bromwich, King's Norton, Manchester, Oldham, and Newport (Mon.) The greatest proportional mortality from measles occurred in Manchester, Hull, Middlesbrough, South Shields, and Newport (Mon.), from diphtheria in Reading, Hanley, Coventry, and Middlesbrough, and from whooping cough in Croydon Tottenham, Northampton, Bristol, Hanley, King's Norton, Smethwick, Stockport, and Oldham The mortality from scarlet fever from "fever," and from diarrhœa showed no marked excess in any of the large towns. Of the 13 fatal cases of small-pox registered in these towns last week six belonged to Liverpool, three to Leicester, and one each to Walsall, Birmingham, Bury, and Manchester There were seven cases of small pox under treatment in the Metropolitan Asylums hospitals on Saturday, Jan. 31st, against numbers declining from 21 to four on the six preceding Saturdays, six new cases were admitted during last week, against four, two, and 0 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2219, 2125, and 2074 at the end of the three preceding weeks, had further declined to 2019 at the end of last week, 227 new cases were admitted during the week, against 223, 192, and 227 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 354, 310, and 411 in the three preceding weeks, declined again last week to 355, but were 59 below the corrected average number Influenza was returned as the primary cause of 25 deaths in London last week, against 39 34, and 43 in the three preceding weeks The causes of 59, or 1 1 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Leicester, Salford Leeds, Newcastle-on Tyne, and 42 other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham St. Helens, Warrington, Sheffield, Hull, and South Shields.

---

[1] THE LANCET Nov 29th 1902, pp 1474 1475

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had risen from 18 5 to 24 6 per 1000 in the eight preceding weeks declined again to 21 3 per 1000 during the week ending Jan. 31st, but was 3 2 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 12 4 in Perth and 17 8 in Edinburgh to 23 0 in Aberdeen and 24 8 in Greenock The 696 deaths in these towns included 32 which were referred to whooping cough, 20 to measles, 13 to diarrhœa, seven to diphtheria five to "fever," and four to scarlet fever, but not one to small pox. In all 81 deaths resulted from these principal infectious diseases last week, against 78, 76, and 102 in the three preceding weeks. These 81 deaths were equal to an annual rate of 2 5 per 1000 which was 0 8 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 24, 32, and 52 in the three preceding weeks, declined again last week to 32, of which 27 occurred in Glasgow and four in Edinburgh The deaths from measles, which had been 15, 12, and 11 in the three preceding weeks, rose again to 20 last week, and included 14 in Aberdeen, two in Glasgow, two in Edinburgh, and two in Leith. The fatal cases of diarrhœa, which had been 18 and 21 in the two preceding weeks, declined last week to 13, of which six were registered in Glasgow, three in Aberdeen, and two in Dundee. The deaths from diphtheria, which had declined from 13 to five in the four preceding weeks, rose again to seven last week, and included four in Glasgow The fatal cases of "fever," which had been three and eight in the two preceding weeks, declined again last week to five, of which three occurred in Glasgow where two of the four deaths from scarlet fever also were registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 152 174, and 183 in the three preceding weeks, declined again last week to 173, were but 32 in excess of the number in the corresponding period of last year The causes of 30 or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 26 8, 30 0, and 28 1 per 1000 in the three preceding weeks, further declined to 24 8 per 1000 during the week ending Jan. 31st. During the past four weeks the death rate has averaged 27 4 per 1000, the rates during the same period being 18 7 in London and 19 1 in Edinburgh. The 180 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 24 from the number in the preceding week, and included 10 which were referred to the principal infectious diseases, against 14 16, and 10 in the three preceding weeks, of these six resulted from diarrhœa, three from scarlet fever, and one from diphtheria, but not one from small pox, measles, whooping cough, or "fever" These 10 deaths were equal to an annual rate of 1 4 per 1000, the death rates last week from the principal infectious diseases being 1 7 in London and 1 4 in Edinburgh The six fatal cases of diarrhœa showed an excess of five over the number in the preceding week, the deaths from scarlet fever which had been one and two in the two preceding weeks, further rose last week to three, while the fatal cases of diphtheria, which had been four and three in the two preceding weeks, further declined to one last week. The 180 deaths in Dublin last week included 27 of children under one year of age and 50 of persons aged 60 years and upwards, these numbers were respectively four and 13 below those recorded in the preceding week Five inquest cases and three deaths from violence were registered, and 65 or more than a third of the deaths occurred in public institutions The causes of 12, or nearly 7 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified —Fleet Surgeons E H. Saunders to Deptford Victualling Yard, and F J Lilly to the *Vivid*, for Keyham Naval Barracks. Dated Feb 2nd, 1903

ROYAL ARMY MEDICAL CORPS.

Captain A. W Hooper, D S O, joins at Aldershot and is posted to the Cambridge Hospital for duty Captain J R. McMunn joins at Aldershot and is posted to the 3rd Station Hospital for duty Captain P Evans (attached Medical Officer with the Grenadier Guards) proceeds to Aldershot for duty

The undermentioned gentlemen to be Lieutenants on probation (dated Jan 31st 1903) —John Grenville Bell, Maurice Guy Winder, Frederick Walter Witney Dawson, John Martin Maynard Crawford, Robert Maurice Ranking, Thomas Seymour Coates, Albert Edward Bathurst Wood, Roland Harley Bridges, Joseph Gatt James Charles Gordon Carmichael Francis O Lambert, James Bernard Meldon, Reginald Cameron Wilmot, Charles Walter Holden, James Ainsworth William Webster, Charles Bramhall, Thomas Ernest Harty, Henry Hubert Swanzy, Kenelym Cobhoun Edwards, John Hay Duguid, Harry Beatty Kelly, George Herbert James Brown, Edward Mansergh Pennefather, Benjamin Howard Vella Dunbar, John Evan Skey, Henry Thompson Stack, Donald Gordon Carmichael, David Ahern, Burnet Graham Patch, and Geoffrey Wallace Grainger Hughes

The undermentioned Lieutenants on probation are seconded under the provisions of Article 349 of the Royal Warrant March 24th 1902 (dated Jan 31st, 1903) —Frederick Walter Whitney Dawson, Geoffrey Wallace Grainger Hughes, and Francis O Lambert.

IMPERIAL YEOMANRY

The City of London (Rough Riders) George Fernandex Mitchell Clarke to be Surgeon Lieutenant. Dated Jan. 20th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) 1st Lanarkshire Surgeon Lieutenant T Kay to be Surgeon Captain Dated Feb 4th, 1903. *Rifle* 1st Lanarkshire Surgeon Captain F V Adams to be Surgeon Major Dated Feb 4th, 1903. 4th (Nottinghamshire) Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment) Frederick William Johnson to be Surgeon Lieutenant Dated Feb 4th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

The London Companies Lieutenant A Granville to be Captain. Dated Sept. 20th, 1902.

MEDICAL STAFF COLLEGE.

The Secretary of State for War has approved of the appointment of the following physicians or surgeons as clinical teachers to the Medical Staff College —

Medicine Dr S J Sharkey (St Thomas's Hospital) and Dr. W Hale White (Guy's Hospital)

Surgery Mr A. Pearce Gould (Middlesex Hospital) and Mr Stanley Boyd (Charing Cross Hospital)

Dental Surgery Mr J H. Badcock (Guy's Hospital)

Dermatology Dr T Colcott Fox (Westminster Hospital)

Laryngology Mr F J Steward (Guy's Hospital)

Midwifery and Gynæcology Dr W R. Dakin (St. George's Hospital)

Ophthalmology Mr E Treacher Collins (Royal London Ophthalmic Hospital)

Otology Mr A H. Cheatle (King's College Hospital)

Pædiatrics Dr A. E Garrod (Hospital for Sick Children, Great Ormond street)

Psychological Medicine Dr M. Craig (Bethlem Royal Hospital)

Major W B Leishman, R.A.M.C has been appointed Professor of Pathology, vice Dr A. E Wright, who has resigned the appointment. Dated Feb 1st, 1903.

ROYAL VICTORIA HOSPITAL, NETLEY

The *Army and Navy Gazette* of Jan. 31st says "At a recent inspection of the Royal Victoria Hospital, Netley, it was found that the annexes were in a very unsatisfactory condition as to sanitation. Owing to their size and shape it has been found impossible to arrange them internally according to the most recently approved designs and requirements without pulling down and rebuilding The cost of doing this is considered to be prohibitive, owing to the large amount which would have to be spent and the great inconvenience which would be incurred. It has therefore been decided to commence on an early date a complete system of changes so as to render the building better fitted for the purposes for which it is used, and votes will be taken in next year's estimate to enable the necessary works to be proceeded with."

THE TRAINING OF SICK BERTH STEWARDS.

The Royal Naval Hospital, Stonehouse, is in future to be recognised as a depôt for probationers to be trained as sick berth stewards, owing to the authorities at Haslar being unable to train all the probationers who present themselves there. The permanent complement of probationers at the Royal Naval Hospital will be 25 and 19 have already entered. Their training is to be supervised by an additional surgeon (Surgeon G Ley, R.N) who will be assisted by an additional ward officer The culinary instruction will be under the direction of the lady cook at Haslar Hospital who will pay periodical visits of inspection. In addition the men are to undergo a daily course of physical drill and gymnastics The period of instruction will extend to four months, at the end of which time qualified probationers will receive their appointments to different hospitals and ships

---

LITERARY INTELLIGENCE —The following new books will shortly be issued by Messrs J and A. Churchill —The seventh edition of Sir William Moore's 'Manual of Family Medicine and Hygiene for India,' published under the authority of the Government of India. The new edition has been thoroughly revised by Major J H Tull Walsh, I M.S. Vol I. of 'A System of Clinical Medicine for Practitioners and Students," giving an account of the diagnosis prognosis, and treatment of disease, by Dr T D Savill. The second edition of Corbin and Stewart's Handbook of Physics and Chemistry" adapted to the requirements of the first examination of the Conjoint Board. A new work on the Microscopical Examination of Foods and Drugs, by H. G Greenish, Professor of Pharmaceutics to the Pharmaceutical Society Vol. IV (Electric Lighting and Photometry) of Groves and Thorp's Chemical Technology The writers of this volume are Mr A G Cooke and Mr W J Dibdin

THE RISE OF BLOOD PRESSURE IN LATER LIFE

To the Editors of THE LANCET

SIRS,—The interesting letters of Sir R Douglas Powell and Professor T Clifford Allbutt in THE LANCET of Jan. 24th (p 265) and 31st (p. 329) respectively, on the rise of blood pressure late in life tempt me to endeavour to supplemen the imperfect remarks which I made when the paper on thi subject was read

In my judgment Professor Allbutt's use of the term increased viscosity of the blood, unless it is intended to be merely figurative, is misleading and it might send young investigators upon a vain research That there is increased resistance to the onward movement of the blood is certain and I have long held that this resistance has its primary seat in the capillaries which would practically be implied i viscosity were the cause but the cause need not be viscosity in a physical sense Attraction between the wall of a capillary tube and contained fluid has an importan influence on the flow of the fluid along it Water rises against gravity in a capillary glass tube, and apparently stil more readily along the stalks of flowers in close contact, as is often seen by its dripping over the edge of a vase by no means full. Mercury does not rise in a glass tube to the level of the mercury outside and presents a convex instead of a concave surface at the top or the column. Water again, would refuse to enter the same tube in which it had previously risen, except under pressure, if the interior of the tube had been greased

It is obvious that the rate of movement of the blood in the capillaries must be affected by the relation between the blood and the capillary wall. The living capillaries are extremely sensitive to the presence of certain substances, organic or saline, and when these are added in minute amount to fluid passing through them the flow immediately diminishes (the vaso-motor nerves having been divided) as was shown many years ago by Dr Sidney Ringer I have long contended with Sir Douglas Powell that products of imperfect metabolism or imperfect elimination, or ordinary products of metabolism may play the part of Ringer's digitaline or lime salts in bringing about capillary obstruction. The clinica observation that obstruction in the peripheral circulation with the consequent increased blood pressure in the arteries can be modified by eliminants is a matter of every-day experience.

Arteriole contraction under nervous stimulation can no doubt increase the obstruction to the blood current immediately and very greatly and, whether partial or general, i can so far raise the blood pressure as to give rise to increased secretion of urine but I cannot accept it as the cause or the persistent high pressure which is the subject of the presen discussion.

Professor Allbutt's object in bringing up for consideration the rise of blood pressure late in life is to call attention to the fact that the condition of the vessels heart, and kidneys found after death in the subjects of this affection is the final result of a long process. The structural changes leading up to this arterio-sclerosis, as it has come to be called are, in a very large proportion of the cases undoubtedly initiated by obstruction in the arterioles and capillaries, and were traced years ago by Sir George Johnson Clinically, the course of the arterial thickening and degeneration can be followed sometimes from youth, often from early manhood, practically always from middle age if i is to be found at all late in life, by the artery being persistently full between the beats of the pulse so that it can be rolled under the finger, by the gradua change which can be recognised in the walls of the vessel when the blood is pressed out of them, and by their increasing tortuosity At first small, from defensive contraction of the muscular coats they gradually yield to the distending influence of the fluid pressure within them and we have ultimately the large, tortuous, inelastic, thick walled, leathery tube of advanced sclerosis. The process cannot only be recognised, it can be modified and checked at any time before advanced degeneration has taken place by suitable diet and eliminants.

It may be added that high blood pressure and the cardio vascular changes incident to it are not necessary effects of advancing years. Many persons at the age of 70 or 80 have arteries as soft and elastic as those of a child. Nor are these changes the only ones met with in old age The artery at the wrist may be thin and compressible when calcareous points, or plates or rings can be felt in its walls, the blood pressure is not high and never has been Again, there may be the special changes in large and small arteries due to syphilis, an account of which cannot now be given

I am, Sirs, yours faithfully,
Brook street, Feb 3rd 1903 W H BROADBENT

To the Editors of THE LANCET

SIRS,—I venture to send you a line on this subject, partly because it is one to which I have contributed somewhat, but mainly because it is of supreme importance that we should have perfectly clear ideas of circulatory phenomena Professor T Clifford Allbutt was good enough to send me a proof copy of the interesting paper which he read recently before the Royal Medical and Chirurgical Society, and were it not for the correspondence which has already appeared in your pages I would not have thought it necessary to crave space for any remarks from me. The correspondence leads me, however, to ask Professor Allbutt if he would kindly make his position more clear to an ordinary mind such as my own Professor Allbutt is such a master at literary garnishing that I am not quite sure I have succeeded in clearly determining the precise character of the viands he has displayed so attractively The particular point regarding which I at present seek enlightenment is as to the precise place he gives to the condition of spasm contraction of arteries, for which I have proposed the term "hypertonus"

In a paper which appeared in THE LANCET in 1901[1] I drew attention to the part taken by this "hypertonus" in determining arterio sclerosis and I so fully realise how important it is that the physician should understand what Professor Allbutt calls "the pathology of processes" that I wish to restate what I indicated then—namely, that certain conditions of blood lead to tightening up and thickening of vessel walls which is often mistaken for true structural alteration, that the recurrence of this "hypertonus" or spasm contraction leads ultimately to structural changes in the vessels, and that along with this "hypertonus" and subsequent structural change there may, or there may not, be raised blood pressure.

The conditions of the blood which lead to this "hypertonus" are, I think, sufficiently indicated by the word *impurity* This is, if I understand aright, Sir R Douglas Powell's position. Does Professor Allbutt accept this reaction of vessels? Or does he contend for some physical alteration in the blood which he terms *viscosity* and which, by impeding its flow, leads to heightened pressure, but to no active contractile reaction on the part of the vessel walls? Whatever the experimentalists may say, clinical observation surely puts it beyond doubt that impurity of the blood causes this contraction of vessels which in the vigorous is usually accompanied by heightened pressure That, however, all tightening up of vessels should be spoken of, or thought of, as heightened pressure or raised *tension* is a fundamental error which we cannot too strenuously seek to correct. In seeking to know "the pathology of processes" it has appeared to me that this vessel response to impure blood was the first step When it is accompanied by decidedly high pressure the thoughtful practitioner recognises it and hence the diet restrictions and the blue pill Without the heightened pressure the condition is not usually recognised, and yet, if my contention be correct, herein lies the beginning of a process the recognition of which would prevent or delay those static manifestations which Professor Allbutt so picturesquely indicates

I am, Sirs, yours faithfully
Edinburgh Jan 31st 1903 WM RUSSELL

THE ANATOMY OF GLENARD'S DISEASE

To the Editors of THE LANCET

SIRS,—I have to thank you for your kindness in affording me an opportunity of perusing Dr Arthur Keith's paper on the Anatomy of Glénard's Disease, which you were good enough to forward to me, and your annotation on which called forth the comment contained in my former letter I must, however, add that my acquaintance with the original document has in no way modified the opinions expressed in my letter regarding the contents of the annotation in question or those contained in that which I afterwards forwarded to you on the subject of the editorial comment which you appended to my published letter This latter comment, indeed, rather surprised me and—emphatically—calls for some reply, on the two fold ground that it misrepresents me and misstates some very important facts in physiological anatomy The critical rejoinder in question consists of three sentences The first is "Dr Knott is criticising a paper which he has not read" I beg leave to state that Dr Knott was doing nothing of the kind he was criticising an annotation on a page of THE LANCET which lay open before him. This fact must be very obvious to everyone who has read my letter The second sentence runs as follows "His remarks as to the action of the diaphragm are mostly academically correct, but had he read the paper he would have gathered that several of his premisses are probably incorrect, particularly that which assumes the relative immobility of the central tendon" I do not propose to ask my critic to offer a scientific distinction between the conditions of being "*academically*" *correct* and *absolutely correct*, or to explain how a statement can be *academically correct* of which the logical premisses are "*probably incorrect*", or how far the "theory of *probabilities*" can be utilised to influence opinion regarding the hard facts of physiological anatomy It is my province to deal with the latter, and the only question in this domain referred to in the sentence which I have just quoted is that of "the relative immobility of the central tendon" The *arguments* of the quotation I take the liberty of relegating to the department of transcendental metaphysics, to which they appropriately belong With regard to the movements of the cordiform tendon during inspiratory expansion of the chest, I had been already aware that one of the mysteries revealed by the x ray illumination was the considerable downward displacement of this fibrous shelf during inspiration I have seen the phenomenon very skilfully and effectively displayed in the course of a brilliant demonstration by an x ray specialist. But I saw at the same time—what the accomplished physicist in question did not appear to have seen—that the descent in question was rather apparent than real, rather relative than absolute, for the *appearance* was produced almost wholly by the *ascent of the ribs and sternum*, which had, of course, the same effect on the objective field thus offered to the observer in an antero-posterior view of a translucent thorax. To my critic, and to all readers who are specially interested in the study of the action of the diaphragm, I would suggest the following experiment There will be no danger, I think, of its being brought within the jurisdiction of the existing law against "vivisection" or even of those for the "prevention of cruelty to children" Let him *purchase* the friendly confidence of a lively "street Arab" of eight or nine, undress him, and place him standing on a table so that the denuded epigastric region will be (approximately) on a level with the visual organs of the observer Let him then induce his youthful friend—under the appetising influence of a further present—to proceed to swallow, with a minimum expenditure of valuable time, three consecutive mouthfuls of dry oatmeal The result will be a perfect display of the aberrant physiological phenomenon familiarly known as "hiccup" He will then have the best possible opportunity of seeing that with each *unmodified* contraction of the diaphragm the six lower ribs are drawn *upwards* and *inwards*, the degrees of displacement increasing from above downwards. This form of displacement is a mechanical necessity which could be foretold by any physiological anatomist, as the translation of every part of the disturbed chest-wall is towards the adjacent part of the circumference of the cordiform tendon of the diaphragm It will also be seen how little real expansion of the chest takes place in this action. Indeed, without any such *objective* experiment, everybody's *subjective* recollections of the operation of *hiccuping* will have informed him how little tendency it produces to *inspiration* of the surrounding air—even if the glottis had been left wide open. The fact that the ribs are so extensively displaced in this movement is, I venture to suggest, an unanswerable reply to the misstatement that the cordiform tendon undergoes much downward change of position *Both ends* of the muscular fibres cannot be *very much displaced* at the same time.

The third, and last, sentence of your criticism reads as follows "As to the assertion that the lower ribs are drawn downwards and backwards by the simultaneous contraction of the diaphragm, intercostals, and serratus posticus inferior it is sufficient to remark that clinicians who have opportunities of watching the isolated actions of muscles in disease are all agreed that the diaphragm *elevates* the lower ribs' The disingenuousness of the attempted argumentation of this sentence can hardly be surpassed, even in the records of legal, or theological, sophistication. Whose I wonder is the *assertion* that the lower ribs are drawn downwards and backwards by the simultaneous contraction of the diaphragm, intercostals, and serratus posticus inferior'? Most assuredly it is not mine, as every reader of my letter can see. I have made the incontrovertible statement that *such is the action of the serratus posticus inferior acting singly* By so acting on the ribs it corrects the influence of the contracting diaphragm which, if left unopposed, would have the effect of *narrowing* the basal section of the thorax, where most expansion is attainable" (I quote my own words) It is of course, superfluous to point out to those who have perused, and understood, my description of the action of the diaphragm that the testimony derived from 'clinicians who have opportunities of watching the isolated actions of muscles in disease' was instruction wasted—so far as the present writer is concerned as well as being conspicuously imperfect.

---

[1] THE LANCET June 1st 1901 p 1519

The contents of Dr Keith's original paper call for comment under many other heads, but I will select only a few On the first page, as the author discusses 'the causes of the variability' of the level of the diaphragm after death, we are told that "the elasticity of the lungs draws the diaphragm up as far as it will yield. The high or low position of the diaphragm depends very little on the distension of the abdomen or of the bowel." Regarding these statements I must say that in the present state of physical and anatomical knowledge they read rather "funny' It is unnecessary of course, to point out that the lungs, or their elasticity have no *direct* connexion with the diaphragm. And every tyro in physiology knows, or surely should know that the expansion of the lungs during inspiration is due to the atmospheric pressure—the regulation 15 lb (14·7) to the square inch—on the *mucous* surfaces when the active contraction of the muscles of inspiration has expanded the chest, by bearing a certain proportion of the same pressure from off the *cutaneous* (external) surface. The external weight lifted (or pushed) off the surface of the body is represented by that used by the internal limb of the gaseous balance in distension of the tubes and vesicles as the pulmonary pleura follows the movements of the walls of the expanding chest. And when the inspiratory muscles have ceased to act the chest walls follow the contracting elastic tissue of the lung till equilibrium or balance between the external and internal pressures is again reached. This atmospheric pressure acts with obvious directness on the circumferential chest-wall in squeezing it—in corset fashion—back to its original position, but it appears to be sometimes forgotten that the *atmospheric pressure is* also *the sole efficient agent in pushing up the diaphragm* during ordinary expiration, and more especially still in that which constitutes the last obvious movement of life.

On page 2 the reader is told that he 'must look upon the diaphragm as a fan shaped digastric muscle.' This appears to be Dr Keith's own special discovery "The central tendon corresponds to the intermediate tendon of such a muscle as the digastric or rectus abdominis" To this physico-metaphysical statement I take leave to take special exception. The preposterous statement that the diaphragm is a digastric muscle cannot for a moment be entertained by any skilled physiological anatomist. It would be less intolerable, indeed to speak of it as a myno-gastric muscle, but even such description would be very unsatisfactory It is rather difficult to comprehend how anyone acquainted with the diaphragm can hold the view that the action of each individual portion is to draw its circumferential attachment towards the spine. Everybody who knows its structure knows that the lateral fibres, on either side, pass from the ribs towards the central tendon and that the only possible effect of their contraction—in addition to reducing the upward convexity—is to draw these yielding bones towards that tendon, that is to say upwards and inwards The fibres attached to the *central leaflet* of course, have necessarily the collective action of drawing the xiphoid cartilage and adjacent cartilages of the lower ribs towards the spine. But this movement may almost be regarded as incidental. The modern geometer "squares the circle' by treating every *infinitely small* segment of the circumference as a straight line. By this—"*quam proxima*" correct—assumption he resolves the space into a series of infinitely *narrow parallel* rectangles. The calculation is then easy But his rectangles must be parallel. The diaphragm undoubtedly may, for fanciful purposes, be looked upon as a structure composed of an infinite number of infinitely small rectangular digastric muscles The rectangular bundles are, however not parallel, and cannot possibly be made so, and, accordingly, the mathematical methods of summation of series" cannot be made to apply

I more especially wonder how it is that in this unusually original thesis Dr Keith has ignored the incontrovertible fact that if the diaphragm acted according to his view—by drawing all its distal attachments towards the spine—it would very seriously limit the space behind the (almost vertical) posterior fibres of the muscle, which is precisely the region where under existing arrangements, the lungs undergo the greatest proportion of expansion. A glance at Fig 1 of his own paper will show this I must also point out the fact that the greater firmness of the chest-wall in *this region renders the wearing of corsets* more tolerable than could otherwise be the case

In the discussion of the "action on the ribs" we are told in regard to that on the abdominal ends of the six lower ribs "this of the three directions in which it expands (? expends) the force of each contraction is the most difficult to understand.' And the writer proceeds to ask, "How is it that the ends of those diaphragmatic ribs *do not* move in towards the origin of the diaphragm from the lumbar region of the spine?" In this connexion I beg leave to state that both difficulties are wholly of Dr Keith's own creation. If the diaphragm were, as he states, a digastric muscle, the phenomenon would be simply impossible to understand, even *after* the *most* careful perusal of his preposterous explanation But as the diaphragm is *not* a digastric muscle endowed with only antero-posterior activity, the difficulty only exists in his own imagination

There are *other* points in this very original paper of Dr Keith's which may very easily be *made to* yield to criticism, but it is probably better to add nothing further to an already too lengthy communication.

I am Sirs, yours faithfully

JOHN KNOTT, M D Dub

THE RAPID TREATMENT OF CONGENITAL HIP-MISPLACEMENT

To the Editors of THE LANCET

SIRS,—The profession having now had time to cool down from the excitement caused by the demonstrations of Professor Lorenz—a little study and calm reflection will show it that miracles must not be expected. Already a long list of failures and very serious accidents have been recorded, and as the public, which is *ignorant of such matters*, will be clamouring for marvellous cures it is necessary that practitioners should be on their guard when advising, and though an effort has been made by medical and other papers to caution the public that complete cures are not to be expected and that the plan is not free from considerable risk it is unlikely that this will reach the very extensive circle to which the operation is known. Hence much may rest with the advice medical men give, though the public is prone to take matters into its own hands when such promising results are expected. Should Professor Lorenz ultimately succeed in demonstrating anything approaching a *complete* cure he will be a great benefactor to humanity and I shall try to be the first to congratulate him In the meantime it seems to me that the odds are heavy against forcible reposition as they were against the open cutting methods and for the following reasons The child walks late, usually about the end of the second year and though she falls about the parents think she will grow out of the trouble, so that these cases are often not brought for treatment until the child has walked some time. Hence the head and neck of the femur are more or less deformed, the acetabulum remains very incomplete the ligaments are overstretched, and some of the muscles are shortened and others lengthened. How is it possible to correct all this by any method? It is quite right to try to do our best to remedy the deformity but to run considerable risk in so doing unless we can guarantee something better than by older plans, seems to me to be scarcely justifiable Of course, if one could promise something more permanent than has hitherto been done and more nearly reaching a perfectly anatomical and functional condition then one may run the risks after explaining their possibility to the parents As this cannot be done it is better to adhere to more gradual plans in the interests of the patients and the surgeon.

As most of the soft parts which normally help to keep the bone in place are torn through before reduction, so-called, is accomplished and as the limbs are put up at about a right angle and kept so for many months, where can the pressure of the femoral head to mould and to enlarge the acetabulum come from? And as the gaps in the torn parts are filled and they become elongated it seems to me that a loose joint, very liable to displacement in almost any direction, is made and consequently secondary displacements—supposing a true reduction has been made—are common Seeing that the head of the femur is larger than the acetabulum and of a different shape how can it possibly keep in place? Even by the open cutting plan when the acetabulum has been enlarged and shaped to the head it very frequently becomes displaced on walking unless ankylosis has occurred, and as in this operation it was found to be a fault to cut the muscles, surely when they are torn through the weakening effect must be at least as great. Moreover, in the "splits" position a large part of the femoral head is downward outside the acetabulum and the small part remaining in contact, even if it do so, would need constant pressure on the sole of the foot or through the knee to produce absorption. Why Professor Lorenz prefers patients aged four years for his operation I cannot understand, for walking increases the mischief and the earlier treatment is undertaken the more hope is there for improvement.

I am, Sirs, yours faithfully,

London W H A. REEVES.

A CASE OF HERNIA INTO THE FOSSA DUODENO-JEJUNALIS

To the Editors of THE LANCET

SIRS,—In THE LANCET of Jan. 24th, p 236, is a paper bearing the above title This paper contains the record of a case of internal hernia, with comments upon the anatomical condition of the parts, but it completely ignores all the work that has recently been published upon this subject. The description given is clear and leaves one in no doubt that the condition found was one of left duodenal hernia. The fossa in which this hernia always lies is known as the fossa of Landzest. The fold bounding the orifice of the fossa in front is known as the plica venosa from the fact that it is raised up by the inferior mesenteric vein for which it forms in early life a sort of mesentery There is neither need nor justification for any new term such as that suggested for the subject is already burdened by a florid and exuberant nomenclature. The hernia does *not* occur into the fossa duodeno jejunalis, indeed, it is doubtful whether a hernia has ever occurred into this fossa. The probability is that the hernia is always congenital and the condition of the fossa in which it lies must therefore be studied in the fœtus or the young child When examined thus early it will be found that a hernia into the fossa of Landzest and the fossa duodeno-jejunalis (the inferior duodenal fossa) are quite distinct. A specimen in the museum of St Thomas's Hospital shows the hernia in an earlier stage than any other museum specimen in this country The anatomy and surgery of the duodenal fossæ are fully discussed in the works of Jonnesco and Brösike and in my own work on "Retroperitoneal Hernia."

I am, Sirs yours faithfully,

Jan. 31st 1903 B G A. MOYNIHAN

BRISTOL AND THE NON-VENTILATION OF SEWERS

To the Editors of THE LANCET

SIRS,—The Bristol argument is really based on a double fallacy The first fallacy is that the Bristol sewers are non ventilated and the exposure of this fallacy by your Special Sanitary Commissioner could scarcely be more complete.[1] The second fallacy is that Brighton and Croydon are ventilated towns. This is not true, either in a legal or a sanitary sense. The Bristol position is therefore doubly false and when we consider what the practical outcome of it is, or may be, it is perniciously false.

In regard to the second fallacy your Commissioner touches the real truth when he says "The example of Bristol seems to indicate that the ventilation of sewers has been so badly managed in some towns that Bristol without any management has obtained [health] results which are quite as good if not better" "Badly managed" is perhaps not the most appropriate term to use in the circumstances, for the trouble does not really lie in "the management" but in the means of ventilation employed in the towns misnamed ventilated.

Brighton and Croydon have been singled out as examples of ventilated towns in this discussion, I presume, because they have adopted, to a large extent at least, the high shaft system Now, if the grid system is inadequate much more so is the high shaft system High shafts are altogether a delusion, having not only all the faults of the grid system but in a greater degree and are therefore less efficient as a means of ventilation under all atmospheric conditions. In addition they are most expensive and unsightly and, as in the present case, fraught with public danger in the false conclusions to which they are capable of leading sanitary authorities honestly desiring to do their appointed public duty The true inference, therefore, to be drawn from the fact that the results at Brighton and Croydon are no better than those at Bristol is that the system at Brighton and Croydon requires improvement and not that the Bristol practice should be set up as a model to be copied by other towns

Your Commissioner's article is a most invaluable one, not only within its own limits but in the questions to which it gives rise. For example, how is it that with such a splendid public health service we are continually seeing the public health break down under severe epidemic foul air disease? I am fully convinced that the key to the answer lies in the fact that the advantages of proper sewer ventilation to public health are not yet understood by sanitary authorities Again, how is it that after so much discussion, scientific research, and costly experimentation the sewage disposal problem is to-day in the unsatisfactory condition it is? Again, I am convinced that the key to the answer is to be found in the fact that the solution of the sewage problem should as I have submitted in my evidence before the Royal Commission, begin with the perfect ventilation of the sewers. Your Commissioner, therefore, has rendered a greatly needed service to the public and I trust it will have an immediate and practical outcome, for in a few weeks the bad sewer gas period will be on us again

I am, Sirs, yours faithfully,

W BROWN

Victoria street Westminster S W Jan 20th 1903

WHY IS NOT SMALL-POX SPEEDILY "STAMPED OUT" LIKE OTHER EPIDEMIC DISEASES?

To the Editors of THE LANCET

SIRS,—This question is often asked, yet the answer is very simple The only true check to the spread of variola among dense communities of people is systematic and efficient vaccination of all infants and the revaccination of children at the school age. Unfortunately this disease alone of all others has been made the sport of political schemers and place hunters who are content to sell their birthright—vaccination—for "a mess" of unseemly pottage. Yielding to the ignorant outcry against the protective influences of sterilised lymph our Government has introduced the bogey of "the conscientious objector" As a practical illustration of the advantages of intrusting compulsory powers for vaccination to a central government authority directly concerned with the maintenance of public health and the prevention of epidemic disease I herewith send some details from a letter just received from a clergyman who has permanent charge of a mission station in the island of Barbados. Fortunately the authorities in this and many of our *distant* colonies are not fettered in their action by *the wire pullers* of political parties, so that whatever is really beneficent for the community can be carried out under the advice of the executive medical officers.

The Government of the island, viewing with alarm the rapid spread of small pox among the native population in what may be called a virgin soil, "acted promptly" and "appointed lay vaccinators all over the island." The payment of 6*d* a head to the wage-earning class gave a great impetus to the vaccination crusade, so that in the brief period of four months 100,000 people had been vaccinated and the epidemic brought entirely under control We do well to contrast this result with the efforts of our Local Government Board to parley with the ignorance of the anti vaccination leaguers. The epidemic which has prevailed for over three years and is now spreading rapidly in the Midlands at a very heavy cost to the rates is the direct result of the pusillanimous action of our executive authorities. What can the proletariat say now in opposition to this perfect *method of providing immunity from* the *deadly* effect of small pox epidemics? The educated classes at least have a claim to protection from the ignorant and even criminal neglect of their poorer neighbours and servants. Is it possible that any of the opponents to vaccination are prompted to take a line directly antagonistic to the expert and scientific conclusions of unbiased investigators because by *the decimating effect of uncontrolled epidemic disease* populations and families are thereby kept in check? The *Times*, in its leading article approving of the establishment of the Imperial Vaccination League, says that "small pox has been shown by a large amount of experience to be in great measure preventable by simple and harmless means."

---

[1] THE LANCET Jan. 17th 1903, p 202.

The disciples of Jenner who can look back to the time when every infant was brought for vaccination as regularly as for baptism and can show the proportionate immunity from the ravages of small pox *pari passu* with the spread of effective measures for stamping out the epidemic, have a right to claim national protection from such a fatal and disfiguring disease. Union is strength. It is important, therefore, *that our leading* statesmen, employers of labour, and those who have the training *of the* young, should coöperate effectually with the medical men and join the Imperial Vaccination League.

I am, Sirs, yours faithfully,
Jan 31st 1903. FREDERICK CHURCHILL, F R C S

MULTIPLE PREGNANCIES

To the Editors of THE LANCET

SIRS,—You may consider the birth of triplets worth recording as the mother and children have all thriven. The triplets were born at 36, Prospect-street, Plymouth, in February of last year and are now healthy and strong babies, all girls The mother also is quite well and the King's bounty was kindly sent to her on my application to the Privy Purse Office through Sir Dighton Probyn. There were three separate placentæ.

I am, Sirs, yours faithfully,
GEORGE BATE, M.R C S Eng

THE NATIONAL HEALTH AND ARMY RECRUITING STATISTICS

To the Editors of THE LANCET.

SIRS,—I venture to think that the views expressed in the leading article in THE LANCET of Jan. *31st*, *p*. 315 headed "An Impeachment of the National Health," being a consideration of the points brought forward by Major-General Sir F Maurice in his article in the *Contemporary Review* entitled "National Health a Soldier's Study,' will commend themselves to the majority of army medical officers having practical experience of army recruiting and the subsequent career of the accepted men when placed under service conditions. Neither medical nor army men will doubt the importance of the question raised, whether as viewed *from* the larger aspect of the general health or from the more limited sphere of the recruiting grounds, but the subject itself is not a new one Several years ago Sir T Crawford published a paper based on army statistics in which he deduced that the physique of the nation was deteriorating—an opinion opposed by the *Times* in a leading article, and among minor fry who have also contributed to the subject I may range myself, the conclusions being embodied in two communications to one of the leading journals in India in 1890 and being markedly in accord with those advanced in THE LANCET in the article referred to Yet, whether new or old, its importance to the community is such that any new light which can be thrown upon it, and especially a presentation of it from the military side by one to whom the War Office and the country may listen, cannot but be acceptable, and, moreover, the desirability of ascertaining the true bearing of the facts is apparent.

Now I think it will be granted that no army can properly *reflect the national characteristics and conditions unless* it be composed of all sections and classes, in *amount in* proportion to their dominance or otherwise in the general population—an essential which conscription fairly carried out may be said to meet—and that no section in its physical and health aspect can be taken *as* a *true representation of* the whole community unless the conditions and circumstances capable of influencing the results are generally present and weigh equally *on* all the *several components*. In the case under consideration the question turns on the validity of the conclusions drawn from the data of *army recruiting* as elucidatory of the national state respecting physique and health. To detail fully all the points which may be advanced against this view would go far beyond the reasonable limits of a letter, but suffice it to suggest the following for consideration. Is it not a fair inference from the statistics that the majority of the volunteers for army service in height, weight, and chest measurement are below the average of our race? and does not a comparison of the recruit as we see him in the streets of the recruiting centres for the line with the passing mass of his fellow countrymen and the experience of the inspecting medical officers as derived from the ranks of the passed *recruits presented to them* at the depots or at joining stations at home or abroad fully corroborate this inference from the figures? Do not the occupation columns show that among those presenting themselves in the recruiting offices labourers and servants largely predominate, while mechanics and artisans are few and *the middle strata rarely figure*, and are *not the localities* from which the majority are drawn the large towns and these giving anything but their best—poor material,- regard it as we may? Would 1000 of our general population, or even 1000 of the classes and sections represented in the *recruiting rooms* taken generally give such a large proportion of rejections from inability to comply with the present physical *standard or from bodily defects* or diseased states (273 75 per 1000 candidates in 1900) as the results for many-consecutive years indicate? Surgeon General Balfour *stated* that "about two fifths of the rejections arise from causes connected with general bad health or feeble constitution, and among *the components* of rejection figure defects and diseases attributable to bad and insanitary dwellings and bad feeding producing an impoverished and poor physique and opposing normal bodily development, constitutional debility, and impairment", but granting that such conditions are too frequently to be met with can *they be regarded as* characteristic of the country as a whole and as producing such a ratio of defects as the recruit sections demonstrate? The more thought is given to the subject the more does the conclusion strengthen that the limited *range of the* community from which the recruit is drawn is such as to furnish *no* adequate basis to work upon on the question of decadence or otherwise of the race and that, to use the words of THE LANCET, "the health statistics of the class desiring *to enlist in the army* are not those of the population of Great Britain as a whole." What Sir F Maurice's proportion of wastage—two only out of five effective soldiers at the end of the second year of service—shows is that the present recruiting grounds *cannot* supply a sufficiency of human material capable of withstanding the pressure of military life. We know well how this poor material succumbs to *foreign* service conditions and disease—what a gap it leaves in the numbers of a regiment required for active service, and the results show that it *ought not to* be subjected to conditions which it is manifestly unable to bear It is true that the two of the five who do get beyond two years of military duty—the survival of the fittest—develop, as a rule, under the fostering influences of good food, good housing gymnastic exercises, &c., into excellent army material, but why, in the face of the experience we now have, we should continue to draw from our present restricted and poor stratum only the necessary human basis on which rest in no small degree the prestige and security of our nation is one of those puzzles to which the average intellect cannot furnish a satisfactory answer Nor is it medical profession can assist in solving this soldier's question of an adequate and efficient recruit supply beyond what is already well known The causes which determine the physical and moral decay of humanity and the conditions which are illustrated in the recruiting offices are already apparent, and granting that the necessities are again set forth and right action taken thereon it cannot be supposed that the results can have any appreciable influence on recruit supply, it remaining in its present narrow limits, within the present generation Meanwhile the army wants are present and urgent and what the recruiting statistics and the accumulated knowledge suggest is that the War Office, facing the facts, should place before the country the necessity of broadening and improving the recruiting area, so making the army a true representation of our race and drawing the recruits from those physical strata of our community fitted to bear the stress of military service, in other words, that the patriotic duty of defending our country should be generally borne and not relegated to sections of which the larger number of their components are from physical and other reasons unfitted to have such a national and Imperial responsibility placed upon them

I am, Sirs, yours faithfully,

Lee Feb 2nd, 1903. Surgeon Colonel (retired), M S

THE SURGICAL TREATMENT OF RHEUMATIC FEVER.

To the Editors of THE LANCET

SIRS,—I have read with considerable astonishment the medical treatment mentioned in an article on the Surgical Treatment of Rheumatic Fever by Dr J O'Conor in THE LANCET of Jan. 24th, p 228, and I am still more astonished to see that in THE LANCET of a week later there is no word of comment on his methods His surgery is no doubt above reproach, but I must crave a few lines to point out that one of the most powerful drugs in the Pharmacopœia suffers quite unmerited disgrace at his hands. In my work, "Uric Acid," published in 1892, I showed that salicylates cured arthritis by eliminating uric acid, and that there are certain conditions—e.g, heat and perspiration—in which they are no longer solvents of uric acid but become precipitants of it. Hence in these conditions they not only fail to do good but may even do great harm and in the fifth edition of the above mentioned book I record a good many cases to illustrate these points. In a word, alkali with heat and sudorifics is a solvent of uric acid salicylate with cold is a solvent of uric acid, but salicylate with heat, sudorifics, and alkalies is not a solvent at all Dr O Conor says "I have no hesitation in stating that this patient's heart has been practically ruined through my delay in operating" This sounds to me very like the old cry of "there is nothing like leather," but in my opinion the heart was ruined by the use of a powerful drug in a manner in which it could not possibly do anything but harm. I can only ascribe this truly terrible, and I have good reason to believe not infrequent, result to the fact that the professional mind has been so completely given over to the hunting of microbes that it has almost entirely lost sight of the solubility of uric acid and the chemistry and physiology that condition this If salicylates properly given fail to relieve the arthritis and bring the temperature to normal in from 24 to 36 hours the disease is not acute rheumatism and the drugs should be given up and then surgery or any other treatment has the field to itself In my book previously referred to I have mentioned that it has even been proposed to call the arthritis met with in India something other than rheumatism because salicylates fail to relieve it A quite rudimentary knowledge of the chemistry of salicylates in their relation to uric acid would demonstrate that salicylates in India are never solvents of uric acid unless the patient is in a freezing chamber and covered only by one sheet. My book has now been 11 years before the profession and yet these important facts are to day almost unknown, and I hear of similar mistakes in the use of the salicylates not in one direction but in all directions. I beg to agree with Dr F P Atkinson[1] that "the greatest friend of truth is time," but meanwhile heaven help the poor patients whose hearts are exposed to the dire effects of these drugs, so powerful for good if given rightly but so powerful also for evil if given wrongly, and whose joints are to be exposed to the surgeon's knife because salicylates which could cure them easily in 36 hours are given under conditions which render all cure by them impossible.

CLEAN MILK *v* BOILED MILK

To the Editors of THE LANCET

SIRS,—Dr Clement Dukes in THE LANCET of Jan 31st, p 331, draws attention to the impairment of the nutritive value of milk by boiling it and its effects on those children who are brought up on it. I wish to indorse his views So frequently have I been convinced that boiled, sterilised, pasteurised milks do not satisfy or nourish *all* children that in my practice I have for some time now advised bottle fed children who showed signs of malnutrition, loss of weight, constipation, and pale flabby tissues to be given unprepared milk, and I can recall no case in which the result was not entirely satisfactory All the children were those of well to-do parents and had the advantage of drinking milk obtained from the best dairies in London where every precaution is taken to prevent the contamination of the milk Still there existed the risk of these children drinking some disease producing milk and if this can be prevented by the rapid cooling process advocated in America it behoves every practitioner to use his efforts to bring this into general use A certain proportion of children who are brought up on boiled milk do certainly thrive, but it is necessary to supplement the milk by the addition of broth or raw meat-juice, &c, at a much earlier period than is required for those children fed on unboiled milk

Brechin place S W Feb 2nd, 1903 F ASHTON WARNER

THE ABUSE OF MEDICAL CHARITY

To the Editors of THE LANCET

SIRS,—My attention has been drawn to an article under the above heading in THE LANCET of Jan 31st, p 314, mainly based upon some statements in a lecture delivered by Mr F H. Bentham at the Bradford Liberal Club a few weeks since referring to the alleged neglect of inquiry as to the circumstances of the parents of children admitted into our hospital, and whilst I entirely exonerate Mr Bentham from any intention to misrepresent the case it will be seen from the following extract from the annual report of the hospital submitted to the meeting of the governors held on Jan. 30th that in his remarks as quoted by you he has unintentionally done so —

> Very many of the cases treated at the hospital are received on the recommendation of the medical gentlemen in the town who naturally satisfy themselves that the position of the families is such as to justify an appeal to the charity but the bulk of the in patients are drafted into the hospital by the honorary medical staff from the out patients department after careful examination and inquiry as to the circumstances of each family and when such circumstances are found not to justify admission patients are invariably refused A further inquiry is subsequently made by the house committee and if deemed necessary other investigations are instituted in the case of *all* in patients and by these means the risk of abuse of the charity is greatly diminished and the board is satisfied that little abuse, if any, prevails

I am, Sirs, yours faithfully,
HERBERT J JEFFERY,
Hon Sec. Bradford Children's Hospital.
Bradford Feb 3rd, 1903

THE TRAINING OF GYNCÆOLOGICAL AND MONTHLY NURSES

To the Editors of THE LANCET

SIRS,—We are directed by the council of the British Gynæcological Society to request the favour of your insertion of the following —

It is generally conceded that the present condition of the nursing world is in many respects unsatisfactory. There is apparently neither any accepted standard nor system of education, nor any reliable method of distinguishing well trained from untrained nurses Women are now able to term themselves 'nurses," and thus may obtain most responsible work in that capacity, when their education and training have been quite insufficient to qualify them to undertake it There is no means by which trained nurses can be controlled or of freeing their ranks from those who prove themselves dangerous to the public and discreditable to their calling

---

[1] THE LANCET Jan. 31st 1903 p 343

The special attention of the Gynæcological Society has been lately drawn to the nursing question Its Fellows employ nurses chiefly for maternity or gynæcological cases, and constant complaints are made of the unsatisfactory character of the present education of such nurses. A most careful investigation of the whole subject on behalf of our society has proved, *inter alia*, that a great number of nurses pass through the larger general hospitals and in still greater proportion through the smaller, without having had any training in the nursing of gynæcological patients, while that of monthly nurses varies from six weeks to three months in duration and is quite inadequate for the responsible duties they are called upon to discharge. For these reasons, the Gynæcological Society has resolved to move in the direction of establishing such examinational tests as will have the effect of bringing about those improvements which are obviously necessary in the education and supervision of gynæcological and monthly nurses The society is strengthened in this determination by the excellent results achieved by the Obstetrical Society of London in the elevation of the education of midwives and by the Medico-Psychological Association in the improvement of the training and work of asylum nurses and attendants, in consequence of the systems of examinations and certificates instituted and carried on by those two societies respectively

The British Gynæcological Society has therefore decided at once to institute examinations and to grant certificates in monthly and gynæcological nursing The three cardinal principles which will be enforced are —1. That every nurse certificated by the society must work only and entirely under the directions of qualified medical practitioners 2. That no woman will be eligible for the society's examination unless she has had sufficient training both in general and special nursing 3. That the society's certificate will be withdrawn from any nurse who at any future time proves to be unworthy of professional trust.

Medical practitioners employing such certificated nurses will thus not only have a guarantee that they are of good character and competent to perform the duties required of them, but also that they are under professional control and subject to rules of professional ethics which, it would seem, nurses generally are at present free to disregard A representative board of examiners has been appointed and the examinations of the society will be held in future once in every quarter —We are, Sirs, your obedient servants,

HEYWOOD SMITH, President.
J H. SWANTON, } Honorary
S JERVOIS AARONS, } Secretaries

Hanover square W, Jan. 31st 1903

MEDICAL CORONERS AND THE APPOINTMENT OF THEIR DEPUTIES

To the Editors of THE LANCET

SIRS —For many years you have advocated the appointment of medical coroners. You have done so for the reason that whilst the law in connexion with coroners' inquests can be, and is, learnt readily by an educated man, the medical details in such inquiries *cannot* so easily be acquired without a previous medical training Medical candidates for vacant appointments as coroners have been successful owing to the large measure of support which you and the editors of other medical journals have given them. One would naturally imagine, therefore, that medical coroners in making their appointments of deputies would continue to support the principle that a knowledge of medicine is an essential to the office of coroner What do we find, however, in London? To quote instances, Dr G Danford Thomas appoints Mr Schröder and Mr Danford Thomas. Neither of these has any medical training Dr F J Waldo also appoints as his deputy Mr Danford Thomas. Strange to say, Mr Troutbeck, a lawyer, appoints a medical practitioner and it is greatly to his credit that he does so I do not question the right of these medical coroners to appoint whom they like and do not question the capacity of the "legal" deputies to carry out their duties faithfully and honestly I merely call attention to the anomaly that medical coroners do not carry out in the appointment of their deputies the principle upon which they received the support of the medical press and their professional colleagues when they themselves were candidates for the office of coroner Is this being true to their profession? Is it not likely to influence the county councils in the future to appoint other than members of the medical profession and to cause them to consider that medical knowledge is not an essential in making such appointments?

I am, Sirs, yours faithfully,
A MEDICAL DEPUTY TO A MEDICAL CORONER.

Feb 4th 1903

THE MEDICAL EXAMINATION OF LUNATICS IN WORKHOUSES

To the Editors of THE LANCET

SIRS,—*Apropos* of your leading article in THE LANCET of Jan. 24th, p 249, on the Medical Examination of Lunatics in Workhouses a recent experience of mine may be of interest. A working man patient of mine became maniacal and on my advice the relatives informed the relieving officer After some delay I received from him a scrap of paper on which he had written a form or certificate to the effect that —— was a person who should be placed under care and control The relatives informed me that if I signed this the relieving officer would come with two assistants and remove him to the workhouse, presumably by force if necessary I naturally declined to sign any such document and sent a message to the effect that if he wished me to certify the man a lunatic I would do so but only on the proper form This eventually he sent and the man was taken before a magistrate and certified in the usual manner On the relieving officer coming to pay the fee he expressed surprise at my objection to sign his form and told me that had he not been pressed for time he would have informed the poor law medical officer who always signed a form in this manner and sent the patient to the workhouse where the proper certificate was filled up by the infirmary medical officer who also pocketed the fee. I found his statement to be correct on inquiry of the poor law medical officer who seemed to think that he was unfairly used but had obeyed the instructions of the guardians. My contention is that the scrap of paper in question is either for the time being a legal certificate of insanity—in which case surely the man who takes the responsibility of signing it should receive what fee there is—or that it is a valueless expression of opinion and the relieving officer who forcibly removes a man from home on the strength of such a document is acting in an illegal manner

I am, Sirs, yours faithfully,
M.D LOND

Feb 3rd, 1903

THE SUPERVISION OF NURSING HOMES

To the Editors of THE LANCET

SIRS,—In view of the scandals that have recently been made public about nursing homes I should be very glad to know whether the medical profession as a body indorses your views as to the desirability of registration and inspection and if there is any chance of active measures being taken to secure legislation on the subject. My own idea is that all nursing homes should be placed under the supervision of the county or borough medical officers of health, though I fear that hardworked body of gentlemen will not support my suggestion. Inspection could be limited to the food and sanitary condition of the house so long as the patients were under constant professional care. For chronic cases some such arrangement as obtains for the medical supervision of certified mental cases could be legally enacted.

I am, Sirs, yours faithfully,
MATRON OF SUBURBAN NURSING HOME.

Jan. 24th, 1903

THE UNIVERSITY OF LONDON AND THE ENGLISH ROYAL COLLEGES OF PHYSICIANS AND SURGEONS

To the Editors of THE LANCET

SIRS,—Mr F C Langford in his letter in THE LANCET of Nov 22nd, 1902, p 1424 wanders off the subject matter to indulge in an unnecessary demonstration of the superior abilities of the Conjoint man as compared with the university man This can only be considered unfortunate Hitherto the whole crux of the question has been taken to be not a matter of personal ability but of opportunity in the case of the two classes of men The larger number of students first enter at a hospital and then consider what qualification they will aim at, these form the Conjoint men, for having paid their fees, &c, they do not feel disposed to retrace their steps and undergo the ordeal of a matriculation and preliminary scientific examination A few men give anxious consideration to the question of a qualification before they enter a hospital, most of such shape their course for the university When I joined a London hospital I was one of four who had decided to go in for the university, the remaining 56 students were Conjoint men. It might be reasonably expected that out of 56 men there would be a greater probability of a display of brilliant work than out of a forlorn number of four men But even apart from any such probability there was no question about the capabilities of the Conjoint men as a whole and of two of them in particular, one of whom took all the hospital scholarships, and the other exhibited consummate ability in the numerous resident posts he held. We university men were a scratch lot. Opportunity and an indulgent Providence rather than personal merit made us what we are.

Mr Langford gives instances of examinational croppers suffered by the intellectually great. We all know of such—the explanation of them belongs to that hazy land of speculation where the voice of the fool alone is heard pondering on the imponderable—a striving and a striving and an ending in nothing To Mr Langford and all other Britishers who are consumed by a wearing anxiety about the quality of a man's qualifications let me say that throughout South Africa we pay no regard to such matters, with us a "doctor" is a properly qualified practitioner By his merits do we judge a man, he may be an M.D of any university, but should he make an ass of himself and a mess of his cases we forthwith catalogue him among the fools Throughout this letter I have spoken of "Mr" Langford—may Providence once more be indulgent to me for thus bending the knee in the house of Baal. Let all Conjoint men take heart from the opinion of a Rhodesian wayside store keeper on university graduates, many of whom float round South Africa like dentists. In a burst of confidence he said to me, 'You know, doctor, 'Varsity men are no good as waiters"!

I am, Sirs, yours faithfully,

Transvaal, Dec 30th, 1902. AFRICANDER.

NOTES FROM INDIA

(From our Special Correspondent)

The Walker Hospital at Simla —Improvements at the Medical College, Calcutta —The Export of Goats' Skins and the Practice of flaying Goats alive —A Successful Crusade against Mosquitoes —The Epidemic of Plague

Among the recent improvements at Simla is the new hospital where Europeans can find improved accommodation during their hours of illness The old and unsuitable wards formerly used have by the gift of the generous donor been replaced by a properly equipped building erected on the lines of the Eden Sanatorium at Darjeeling Mr Walker's handsome gift was of the well known Gordon Castle Estate, but Government acquired this for administrative buildings, and the present site of the new hospital has more suitably been found on a spur situated at the back of Snowdon. The main building, consisting of a central portion with cross arms or wings at the end, is two-storeyed. It is very largely composed of timber, but ample provision has been made against the risk of fire

The new pathological and physiological building to be added to the Medical College, Calcutta, also requires notice. It forms one more step in the reconstruction of the college upon modern lines. The first improvement undertaken was the anatomical block and then came the chemical block, both of which are in full occupation. The present addition is three-storeyed and is designed to harmonise with the two others. The entire fitting up has been carefully thought out and will render this building when completed the best institution of its class in Asia It is anticipated, however, that the beginning of 1904 will be the earliest date by which it will be ready for use. On the ground floor will be rooms for normal histology and physiological chemistry and an experimental class-room, besides small rooms for the professors, diagrams, photography, &c. On the first floor will be rooms for morbid histology and bacteriology besides the large theatre The second floor will be chiefly taken up with the museum

The common practice of flaying goats alive in different parts of India has been nurtured by the demands for long necks in the skins. The export of goats' skins is enormous and a certain percentage—said to be only small—have long necks. The religious method of killing is to decapitate by a cut through the neck, but for long necks an incision is made round and under the jaws and over the top of the head, the skin being turned back, and then the head severed from the body This, of course, is horrible cruelty and one could wish that only 1 per cent of exported skins as stated was at least not exceeded, but this is doubtful The practice is being actively investigated by the honorary secretary of the Calcutta Society for the Prevention of Cruelty to Animals, and in a note he urges on consumers or users to reject long necks and to alter the bases of measurements, fixing it from the base of the neck instead of from the apex If the trade would coöperate in this direction there would be no inducement for the continuation of this atrocious form of cruelty This question deserves to be ventilated throughout the whole of Europe and especially in the countries to which these skins are exported

An effective crusade against the anopheles mosquito has been carried on during the past year at Jaidulpur in the Central Provinces The local conditions were particularly unfavourable in consequence of numerous tanks and open drains, but mosquito brigades have set to work actively Formerly 28 per cent. of the patients in the hospitals were cases of malaria fever, but during the last five months the percentage has dropped to 11 55 per cent.

Upwards of 16,000 deaths from plague were recorded throughout India for the week ending Jan. 10th. This is an increase of 511 on the previous week and 5829 more than in the corresponding week of last year The Bombay Presidency reported 8340 deaths, an increase of 1045, the Bengal Presidency reported 1854, an increase of 92, the United Provinces 1712, an increase of 52, and the Madras Presidency 596, an increase of 151. The Punjab alone reported any decrease—viz., from 2238 to 1736 Other returns of importance are Calcutta, 29 deaths, Bombay city, 352 deaths, and Karachi, 25 deaths In all three of these cities plague is increasing, especially in Bombay, where 169 additional deaths occurred during the past week. The Hyderabad and Mysore States, the Chitral Provinces and Berar, continue to be infected. A commission has been appointed to inquire into the lamentable accident which occurred in the Punjab in connexion with inoculation. Without any disparagement to the members appointed I think that officers should have been selected who are well acquainted with the methods of manufacture of the prophylactic serum and of the practice of plague inoculation. The President of the Commission is a judge, not a scientific expert, and in an investigation of this kind it is difficult to see where his abilities can be utilised.

Jan. 15th

BIRMINGHAM

(From our own Correspondent)

Health of the City

The returns of the medical officer of health, Dr A. Hill, for the week ending Jan. 31st, show improvement in some directions and some cause for anxiety in others. The death rate was 17 1 per 1000 against 21 4 the previous week, but, on the other hand, there are an outbreak of small pox and a large number of cases of scarlet fever There are now 18 cases of small pox in the isolation hospital, one patient having died during the week. 66 fresh cases of scarlet fever were notified during the week, the total number in the hospital being 475 The type is not a virulent one, fortunately There is no doubt that the dissemination of small pox is caused mainly by tramps who occupy the tramp wards at workhouses and by the common lodging houses of the city The difficulty of dealing with these carriers of contagion is almost insurmountable. Of course they are isolated and complete disinfection is carried out as soon as the discovery is made, but in many cases the mischief has already been done. In connexion with this subject a circular letter, signed by the Lord Mayor, the chairman of the health committee, and the medical officer of health, has been addressed to the medical practitioners of the city, pointing out that chicken pox has been added to the list of notifiable diseases, the object being that all cases of chicken pox in children over seven years of age may be visited by the medical superintendent of the hospital with the view of promptly discovering any modified case of small pox that may be among them. That this course has proved to be justified is shown by the fact that in several instances cases of small pox were found. Of course, all these examinations are made in consultation with the ordinary medical attendant or with his consent

The New Licensing Act

One of the most emphatic attempts at a needed social reform is exhibited in the powers of the new Licensing Act in dealing with drunkards and drunkenness. Some typical instances have been already dealt with by the magistrates of the city where the requisite number of previous convictions have been proved. Several separation orders also have been obtained by the husbands of inebriate wives.

St John Ambulance Association.

The annual meeting of the Birmingham branch of this association was held on Jan 21st under the presidency of the Lord Mayor The accounts showed a surplus of £19 odd. Four classes had been held during the year in connexion with manufactories and the attention of employers of labour was called to the importance of inaugurating classes in connexion with their works. It was pointed out that the Birmingham centre was formed in 1880 and that it had qualified nearly 8000 men and women in rendering first aid Last year 22 classes had been held and 284 members had received certificates. The Lord Mayor was of opinion that it should be made compulsory that most public servants should hold certificates. The advantages and the sense of security he thought would be obvious. The Birmingham corps had seven divisions with a membership of 150, which it was considered should be greatly increased. Votes of thanks to the medical officers and others were passed unanimously

The Women's Hospital

A strong appeal has been issued for funds towards the building of a new women's hospital in the city At a meeting held on Jan 15th the following resolution was passed —

> That the meeting is of opinion that it is necessary to build a new hospital on freehold land as soon as possible with beds for 40 patients and also a new convalescent home with accommodation in proportion.

The reasons for desiring additional space and modern equipments were pointed out by the President who stated that a sum of £30,000 was needed to realise their expectations. Already large sums have been promised and the enthusiasm and energy with which the work has been commenced have occasioned much encouragement.

Midland Counties Home for Incurables

The annual report, read at a meeting on Jan. 16th, showed that while the need of this institution continued to increase in every direction, the expense had been kept within the income for the year This fact in the history of such homes cannot but be regarded as satisfactory The subscriptions for the year amounted to £2245 the donations to £289, and the patients' payments to £2487 The total amount collected for the third section extension fund is £2209 but in regard to this extension the committee recommended the governors to rescind the plans for a chapel and recreation room in one building and to authorise the work being undertaken in two separate portions, the nurses dining room and the recreation room being put in hand at once A new plan had been prepared containing a room suitable for week day entertainments and also when required for Sunday afternoon services. Various legacies were announced and votes of thanks were accorded.

The Queen's Hospital.

At a meeting held on Jan 30th Dr J G Emanuel was elected to the new post of casualty physician and Dr Arthur Stanley Barnes was appointed pathologist to the hospital.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Liverpool Royal Infirmary Annual Meeting Changes in the Honorary Staff

THE annual meeting of the friends and supporters of the Royal Infirmary was held in the board room on Jan. 29th, Mr T Sutton Timmis (the President) occupied the chair The committee lamented the loss by death of Mr William Rathbone, its senior member, whose election dated back to 1860 He took an active part in building the present infirmary and to him the charity was chiefly indebted for the existing admirable nursing system. Under the operation of the laws Dr Richard Caton's term of office expired in July, 1902 Appointed in 1886, he worked for 16 years, to the immense benefit of both patients and students, and had earned the friendship and respect of all. So also in November, 1902, after a devoted service of 26 years, came Sir William Mitchell Banks's retirement in the same circumstances Both as a surgeon and a professor his long connexion with the hospital had been of inestimable value. By an arrangement with the committee, and by the courtesy of his colleagues, ten beds in the surgical wards are still at his disposal, whereby the benefit of his advice and experience will be retained for some time longer To the posts of honorary physician and honorary surgeon, rendered vacant by the retirement of Dr Caton and Sir William Banks, Dr John Hill Abram and Mr George Gibson Hamilton had been respectively elected Dr E. E Glynn and Mr T C Litler Jones had been elected to the vacancies caused by the promotion of the latter two gentlemen So great had been the progress within recent times of surgical science that a rearrangement of the operating theatre was deemed wise. The two new theatres that had been constructed through the munificence of Mr Ralph Brocklebank were opened in October last by Sir Frederick Treves. They had in practice proved, as anticipated, all that could be desired. Each honorary surgeon had now a separate theatre, thus the harassing delay to patients awaiting operation was avoided, while every modern appliance to insure their speedy recovery had been adopted. The number of major operations had risen from 770 in 1881 to 1372 in 1901 Through the generosity of a member of the committee an electrical department for the treatment of skin diseases had been opened. 3415 patients had been treated in the house and 20,441 in the out-patient department, giving a total number of attendances of 78 017 The average number resident was 244 The expenditure had been £14,800 and the receipts £12,957 The debt now stood at £2809 The chairman of the committee (Mr E. Kewley) made a feeling allusion to the death of Mr Hamilton B Gilmour which occurred on Jan. 24th The late Mr Gilmour had been closely connected with the infirmary for over 30 years and was chairman of the general committee for 18 years Mr James Lister was elected as President for the ensuing year Mr Lister is also an old member of the committee, having served on that body for nearly 30 years. Mr Sutton Timmis (the retiring President) announced his intention of contributing 200 guineas to the funds of the charity

Another Increase in the Number of Small pox Cases

According to the report of the medical officer of health presented to the health committee on Jan. 29th, it appeared that there were 274 cases of small pox under treatment in the corporation hospitals. 51 fresh cases were reported, as against 42 in the previous week. The outbreak in the Prescot workhouse and neighbourhood is, happily, abating 23 cases are under treatment at Wigan.

Liverpool School of Tropical Medicine Dr A. Logan Taylor's Visit to the Gold Coast

The Governor of the Gold Coast, Sir Matthew Nathan, in a letter dated Accra, Jan. 10th, acknowledges that so far as he can judge from official and non-official opinions, Dr Logan Taylor, who had been sent out by the Liverpool School of Tropical Medicine, had already effected considerable improvement in the sanitary condition of Cape Coast Castle, and asked that he might continue as health officer there until the arrival of one of the assistant colonial surgeons who takes considerable interest in sanitary work and who was due to return to the colony about the middle of March.

The Visitor of the General Medical Council for 1903

I AM pleased to announce that Professor Sir George Hare Philipson has been appointed by Sir William Turner, the President of the General Medical Council, on behalf of the General Council of Medical Education and Registration of the United Kingdom, the visitor during the year 1903 of the final examinations of the University of Edinburgh.

Social Medical Meetings in Gateshead-on Tyne

The sixth annual dinner of the Gateshead Medical Association was held on Jan. 14th at the Royal Hotel. The President of the association, Dr H. J Gilbert, occupied the chair and was supported by Mr John Todd who acted as vice chairman Nearly all the medical practitioners of the town were present and a most enjoyable evening was spent About 40 members and guests sat down to dinner, among the guests being Mr Rutherford Morison of Newcastle and Dr H B Densham of Stockton on-Tees The chief toast of the evening—"The Gateshead Medical Association"—was very ably proposed by Mr Rutherford Morison who spoke of the many important advantages derived from such an association and the unfortunate lack of business principles in medical men generally, and he bestowed a well deserved eulogium on Dr Alfred Cox who was the pioneer of the association, and to whom the great success which attended it in bringing together the practitioners, both medically and socially, was due. He also said that Dr Cox was not only the pioneer but the moving spirit in the medical organisation in the counties of Durham and Northumberland, which organisation had recently been attended with very great success and served as an example to the rest of England.

Gateshead Dispensary

The annual full and fancy dress ball in aid of the Gateshead Dispensary was held on Jan. 16th in the town hall. More than 200 guests were present, the majority being arrayed in fancy dress It was the most successful gathering which has been held for some years, the company including a considerable number of medical men. Mr Andrew Dougall and Mr A. White acted as honorary secretaries

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Carmarthen Asylum

WHEN the Commissioners in Lunacy visited the Carmarthen Asylum in the autumn of last year they reported that the institution was overcrowded and that there were 26 patients in excess of the number for which there is accommodation In his annual report the medical superintendent (Dr E Goodall) states that at the end of 1902 there were 650 patients in residence, the asylum being full on both sides, but that if the patients from other counties than those for which the institution is provided—viz, Cardigan, Carmarthen and Pembroke—were excluded there would be 33 vacancies. If patients are taken exclusively from the three counties the present accommodation will suffice for another five or ten years. There are 42 private patients in the asylum and as a result of a recommendation contained in Dr Goodall's previous annual report a sub-committee has had under consideration the further provision of accommodation for this class of patient. It was recommended by the sub-committee that from 15 to 30 acres of land should be acquired and that an additional block of buildings should be erected, but the committee of visitors refused to carry out the recommendation. The medical superintendent deals in his report with the question of the boarding out of harmless patients and appears to be of opinion that the weekly cost would not be less than *10s* per patient, so that in the case of the Carmarthen Asylum, where the average weekly cost is less than *8s 9d*, no actual economy would result from the adoption of the system. Dr Goodall considers some of its advantages to be that convalescents are removed from the asylum buildings with their associations and disturbing sights and sounds and are placed in a half way house on the road home, while enfeebled chronic cases are provided for under more home-like conditions. In 1901 tuberculous diseases accounted for 40 per cent. of the total number of deaths in the asylum, but in 1902 this percentage was reduced to 29

Newport Medical Society

At the meeting of the Newport Medical Society held on Jan. 29th it was recommended that several hand ambulances should be provided at suitable centres in the town for the removal of accident cases to the hospital. Dr William Sheen of Cardiff gave a description of the diseases of the umbilicus with a summary of the abnormal conditions met with there He referred to the meagre manner in which the subject was dealt with even in the latest and standard text-books, and said that he had been at some pains to collect data and cases of the various conditions found He classified the morbid conditions under the following headings —Hæmorrhage, septic and infective processes, syphilis *fistulæ* (fæcal, urinary bilious, and purulent), conditions dependent upon the persistence of the omphalo-mesenteric duct and vessels, conditions dependent upon the persistence of the urachus, hernia, and tumours (innocent and malignant) In connexion with infective processes Dr Sheen referred to the case of the island of St Kilda in which about 80 per cent of the infants died from the "nine day fits," a condition which was found to be due to infection of the umbilicus with the tetanus bacillus

Newport and Monmouthshire Hospital.

The new buildings connected with the Newport (Mon) Hospital were first occupied last year, so that the annual report of the directors of the institution is of more interest than usual The number of in patients treated during 1902 was 898, an increase of 172 over that of the previous year The expenditure amounted to £4596 and the receipts to £5863. Included in the latter sum are £1400 collected weekly by the working men of the town. There is still one of the hospital wards unoccupied.

Royal United Hospital, Bath

The annual meeting of the subscribers of this institution was held on Jan. 28th under the presidency of the Mayor The medical report stated that during 1902 the in patients numbered 1389 against 1321 in 1901. 7891 out-patients were attended, a decrease of 103 as compared with the previous year 349 patients were visited at their homes as compared with 245 in 1901 The financial statement showed that the total receipts amounted to £5774, and that the total adverse balance now amounted to £4297 The meeting unanimously decided that in future, as far as advisable, a charge shall be made to those in patients who can afford to pay something The fee shall not exceed two guineas weekly and all such cases shall be treated in the general wards on the same status as ordinary patients A resolution, which was the unanimous recommendation of the medical staff—namely, that the resident medical officers shall discontinue to visit patients at their own homes—was agreed to

Bath Water supply

Allusion has already been made in THE LANCET of Nov 1st, 1902, p 1225, to the proposals of the Bath corporation for increasing the water supply of the city At the end of October last the city council decided by 13 votes to seven to promote a Bill in the ensuing session of Parliament to enable works to be carried out at an estimated cost of £44,000 but a persistent minority of the inhabitants has endeavoured, fortunately without success, to defeat the desires of the majority Although at the statutory meeting of the ratepayers which was held on Dec 20th a resolution consenting to the promotion of the Bill was carried by 12 votes to 52 a poll was demanded the result of which shows that 6344 ratepayers are in favour of the Bill and that 1591 are against it. The action of the city corporation is thus sufficiently justified

Feb. 3rd

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

Queen Victoria's Jubilee Institute for Nurses

THE report of the council of the Scottish Branch of Queen Victoria's Jubilee Institute for Nurses for the year 190 shows that the work of that admirable and most valuabl stitution has been progressing and developing in a satisfactory manner. The annual income, however, has not creased proportionately to the demand for nurses. At the id of October 1902, the Scottish council was responsible r the maintenance of 51 nurses and probationers. During ie year 18 candidates entered the training home for the quired month of probation before receiving hospital training, of these five failed. 34 probationers who had received ospital training entered the home for six months' district aining, of these one failed. 31 nurses completed their aining. Two nurses completed their training in the Higgin- tham Home, Glasgow, and two in the Dundee Home. ectures were given during the year on hygiene, fevers, nd diets, obstetrics, district nursing and sick cookery. 31 urses on completion of their training were engaged from ne home by local committees. 30 nurses resigned during ne year. 11 new branches were established by local comnittees and on showing that the required conditions were lfilled were affiliated to the institute. The superintendent nd assistant inspector made 176 inspections of single nurses nd small homes. There are now 224 Queen's nurses in cotland under 150 affiliated branches, of which 24 are under wo county associations. With regard to the work done uring the year in Edinburgh by the nurses from Castle-errace and by the two nurses in Leith the visits paid umbered 103 and 474 respectively. There was during he year an increase of 397 cases and 10 686 visits. The uperintendent reports that the work had been very heavy s there had been no addition to the staff to meet the ncrease in work. The nursing of maternity cases showed great increase, while there had also been a considerble number of operation cases. The ordinary income mounted to £2334 12s. and the ordinary expenditure to 3164 17s. 11d. The council regrets that it has again to raw upon its small amount of available invested funds o meet this excess of expenditure. It is hopeful that he special appeal at present being made in the interests f the Institute by the Duchess of Buccleuch on behalf f "The Queen Victoria Memorial Endowment Fund" will be largely responded to. A summary of the work done y the Edinburgh nurses gives the following figures as howing by whom patients were recommended:—from ispensaries 720, from hospitals 233, by clergy, 51, by istrict visitors 156, by patients and their friends, 285, by medical men, 3240. Of the cases nursed 1725 were medical, 1122 were surgical, 393 were gynæcological, and 1402 were obstetric.

Induction of the new Principal of the University of Edinburgh.

A meeting of the Senatus of the University of Edinburgh was held in the Senate Hall, Old University Buildings, on Jan. 31st, when Sir William Turner was formally inducted as Principal of the University in room of Sir William Muir, resigned. The proceedings were in private. Professor A. Crum Brown as senior professor presided and the senior dean Professor Chrystal presented the new principal to the president of the Court. The secretary to the Senatus, Professor Sir Ludovic Grant, Bart., read the commission appointing Sir William Turner to the principalship and at the completion of the formal induction ceremony his late colleagues in the professoriate cordially welcomed Sir William Turner as the new principal.

The Chair of Anatomy in the University of Edinburgh.

For the remainder of the winter session the entire responsibility and management of the anatomy department in the University of Edinburgh will be in the hands of Dr. David Hepburn who at present holds the post of lecturer in regional anatomy and principal demonstrator of anatomy in the department. This arrangement has been made in order to enable Sir William Turner to devote his attention to his new duties as principal.

Edinburgh Royal Blind Asylum and School.

At a meeting of the directors of the Royal Blind Asylum and School, Edinburgh, held on Jan. 26th, the directors after other business considered a report from Dr. George Mackay, ophthalmic surgeon to the Royal Blind Asylum, on the eyesight of the women and children at the West Craigmillar Asylum. The report concluded by stating that nearly one-third (31·8 per cent.) of all the cases admitted owed their blindness to purulent inflammation of the eyes occurring in the newly born through want of simple precautions in cleansing the eyes immediately after birth. The directors agreed in view of the great significance and importance of this statement that Dr. Mackay's report should be sent to all local dispensaries and medical institutions.

Health of Aberdeen: the Increase in Infantile Mortality.

At a meeting of the Aberdeen Secondary Class Teachers' Association on Jan. 28th Professor M. Hay delivered a lecture on the Increase in Infantile Mortality. After quoting Addison's Vision of Mirza on the hills of Bagdad, he pointed out that this vision of the bridge of life could be dealt with in a scientific manner, and this he proceeded to do by means of diagrams in which he showed that the death rate in the first year of life in Aberdeen was enormously high, but that there was a reduction in mortality during the school age and at other periods during the last 25 and 50 years. In Aberdeen, as he had pointed out in reports to the town council, the infantile mortality showed an increase instead of a decrease, having within the last 25 or 30 years risen from 145 to 176 per 1000 per annum, or one in six of all born. If this high rate of mortality existed among lambs or calves or foals it would have attracted greater attention long ago. Professor Hay proceeded to point out that, while many of these deaths of infants were due to prematurity and defects of development, yet a great proportion was due to the increased use of the feeding bottle as a substitute for nursing and the indiscriminate feeding of infants with food which, while suitable enough for adults, was as poison to them. Then the chances of children in the first year dying from whooping-cough and measles were enormously greater than at a later period. While no Scottish or Aberdeen mothers would willingly injure their children, yet there was a vast amount of ignorance and thoughtlessness amongst them. To him the time did not seem to be far remote when the question of the preservation of infants would become one of State importance. What they needed for themselves and their children was more fresh air. That was much required in their houses, especially in their poorer houses. He believed that the time was coming when it would be regarded as foolishness to have windows continually shut. On the motion of Herr Hein, a hearty vote of thanks was awarded to Professor Hay for his excellent lecture and Professor Hay, in acknowledging this, stated that while he preferred the natural system of ventilation for houses there was not sufficient cubic space for it in schools, and therefore artificial ventilation had to be resorted to.

Aberdeen University Medical Society.

A meeting of this society was held on Jan. 23rd, Mr. G. G. Macdonald being in the chair.—Mr. W. W. Lawson described a case of Congenital Cystic Hygroma which occurred in a child and filled up all the triangles on the left side of the neck, extending round to the right side also. No operation was performed and the child died from dyspnœa.—Mr. W. Clark Souter described a case of Suppurative Perforating Appendicitis which occurred in a girl aged 13 years. Constipation varied with occasional diarrhœa had been observed for six weeks previous to treatment, but symptoms of appendicitis did not present themselves till within four days of operation and death. The appendix was found to be ulcerated almost to its base, near which it was perforated. A fæcal concretion of the size of a raisin was extracted.

Feb. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Dublin.

ON Feb. 2nd a woman believed to be suffering from small-pox was removed from a tenement house in Church-street to the isolation wards, North Brunswick-street. There were 25 other persons in the house from which she was removed and they have all now been conveyed to the refuge in Nicholas-street while the house is being disinfected.

Cork-street Fever Hospital, Dublin.

At a meeting of the committee of management of Cork-street Fever Hospital which took place on Jan. 29th Dr. Herbert U. Byrne was elected visiting physician.

Jervis-street Hospital, Dublin.

Dr. Edward FitzGerald Stapleton was elected by the governors surgeon to Jervis-street Hospital in room of Mr Austin Meldon who has resigned

The Belfast Maternity Hospital

At a meeting of the governors of the Belfast Maternity Hospital, one of the oldest medical charities in the north of Ireland, held on Jan 27th, Professor John W Byers was elected physician. This hospital has recently been placed upon a new constitutional basis and it is intended in a short time to remove from the present situation in Clifton-street and to erect a new and more commodious lying in charity The appointment of Professor Byers has given great public satisfaction, as it is at this hospital that the students of the Belfast Medical School mainly obtain their midwifery practice, and it was felt by the authorities of the hospital that the occupant of the chair of obstetrics at Queen's College, Belfast, should, as is the case in Edinburgh, be a clinical teacher at the Maternity Hospital

Ulster Medical Society

The third meeting of the session of this society was held in the Medical Institute, Belfast, on Jan 29th Dr John Campbell, the President, being in the chair Dr Henry Whitaker (medical superintendent officer of health) opened a discussion on the Notification of Infectious Diseases and there was a large attendance, as in the circular summoning the members it was stated that the council of the society had heard with great regret that grave charges had been made in the City Council and elsewhere with regard to the notification by medical practitioners of illnesses as infectious without sufficient grounds The council of the society felt that it had not sufficient evidence to warrant it in taking any direct steps in this matter, but with a view to prevent in future such practices, if they had occurred through carelessness or otherwise, it had arranged this discussion on the working of the Notification Act Members were therefore specially requested to be present at this meeting, as such allegations seriously involved the honour of the profession. In his address Dr Whitaker pointed out how cases had been notified on insufficient grounds. In the subsequent discussion some of the members thought the matter must be left in the hands of the public health committee, as without full evidence the society could not take action, and it was elicited that of three medical men who were blamed one was dead and only one was a member of the society Some of the speakers pointed out that the Notification Act was carried out most imperfectly, that far more cases of typhus and typhoid fever occurred than were reported, and that medical men in better class practice did not report cases as they should, and that the part of the Act requiring heads of households—as well as the medical men—to notify cases of infectious diseases was completely in abeyance. Further, some of the speakers found fault with the proposed situation of the infectious diseases hospital, owing to its distance from the city Finally after a long discussion, which showed clearly that the Notification of Infectious Diseases Act in Belfast was by no means fully in force, it was decided to ask the council of the Ulster Medical Society to consider the question of the action of members of the medical profession in this matter, and the honorary secretary was instructed to ask the public health committee to provide details of cases in which there had been defects on the part of medical men in carrying out the provisions of the Act —Three new fellows and two new members were elected, and Dr William M. Killen showed a series of interesting eye cases

The Belfast Hospital for Sick Children.

At the thirtieth annual meeting of the subscribers to this institution it was reported that during the year 1902 there were treated in the wards of the hospital 694 cases with 26 deaths, while 5916 new cases were treated in the extern department (2736 medical 1364 surgical, 1196 eye and ear, and 620 dental) The number of patients treated in the wards was larger than in any previous year in the hospital's history A large number of senior students are in attendance at the hospital cliniques It is to be regretted that the financial condition is not satisfactory, as there had been spent £650 more than was subscribed, and the year before a sum of £230 had been spent more than the income. The deficit is largely due to the fall in the number of legacies, but as Lady Jaffé (the wife of the treasurer) has offered to give £100 if before July 1st ten others will join her in giving similar amounts it is hoped that the institution will soon be out of debt

Rainfall in January in the North of Ireland

January has been the wettest first month of the year since 1886, as the rainfall has been 5 33 inches, falling on 24 days.

Health of Belfast

At a meeting of the city council held on Feb 2nd it was reported that the death rate (24 2 per 1000) was rather higher than usual, due almost exclusively to a bad epidemic of measles. There were 145 deaths from zymotic diseases, 106 from pulmonary consumption, and 218 from diseases of the respiratory organs. In the corresponding period of last year the death rate was from all causes 20 12.

Action against a Medical Man Alleged Neglect.

At Bandon quarter sessions, before County court Judge Bird, the remitted action brought by Patrick Byrne, labourer, of Innishannon, against Dr John Reid was heard. The plaintiff sought to recover damages on the grounds that the defendant had treated him negligently and had not exhibited sufficient medical and surgical skill. The plaintiff suffered from fracture of two or three ribs and dislocation of the collar bone, the result of a fall into a quarry He sent for the late Mr Alcock who was the dispensary medical officer of the district, but as Mr Alcock was absent on leave Dr Reid attended as his substitute. The plaintiff in his evidence alleged that Dr Reid had promised to call on the following day and had not done so, the bandages had loosened and he suffered great pain He stated that he still suffered from pain in the arm and that he could not work as well as previously Dr Reid gave evidence to the effect that he had adopted the usual methods for treating injuries of the kind and impressed emphatically on the plaintiff that he had sustained an injury which could not be completely cured and that he should not afterwards blame him (the defendant) for the result. Professor C Y Pearson of Cork stated that the result of the treatment of this class of injury was scarcely ever successful, the muscles of the upper part of the plaintiff's arm were well nourished, from which he concluded that he had been using it pretty freely Dr J Cotter of Cork gave similar evidence and the judge having summed up, the jury, after deliberating for about 40 minutes, brought in a verdict for the defendant. Judgment was accordingly marked for the defendant with costs

Chloral Hydrate Poisoning Important Observations by the Coroner

Mr Coroner Murphy held an inquest at Cork recently regarding the death of a commercial traveller It appeared from the evidence that the deceased had been drinking recently and had been in the habit of taking chloral. His wife went to Cork to nurse him and on calling him in the morning got no answer, and it was then found that he was breathing his last. A medical man who was called in stated that death was due to the action of chloral hydrate on a weak heart. The coroner commented on the fact that the deceased had obtained the prescription for the chloral hydrate as far back as one and a half years ago and that it had been compounded several times since by druggists in various parts of Ireland He said that the druggists must have known that the drug was a dangerous one and he considered it a great shame that they should have gone on supplying a medicine of the kind without insisting on the necessity for the deceased to procure more recent medical advice as to the suitability of the drug for the treatment of his case

PARIS

(FROM OUR OWN CORRESPONDENT)

The Overcrowding of the Medical Profession and Compulsory Military Service.

THE constant increase in the number of medical men in France, which makes the future of medical men appear very gloomy, has given rise to much thought and many are the reasons assigned for this increase One reason which is very commonly mentioned is the law concerning military service which makes it compulsory upon every French male who has attained the age of 21 years to make out three years' military service. There are, however, certain persons exempted from serving three years and such persons are excused with one year's service. Among them are young men who are entering the liberal professions, it being considered by the law that to take three years from a young man's course of study would seriously prejudice his future and would diminish the cultivated portion of society Two of the professions thus dispensed are medicine and civil law, and accordingly there is a rush into these two professions of young men who do not want to serve three years as a soldier The profession more sought after of the two is medicine, it being thought that a medical man can begin to make money for himself sooner than a lawyer can and also that the latter profession is more risky than the former So marked appears to be the relation between the overcrowding of the medical profession and the one year's military service that medical men are giving vent to the wish that for the future medical students shall not be dispensed from the three years service. Dr. Brouardel, who has just brought out a very interesting book dealing with the medical profession at the commencement of the twentieth century, argues that the military question has nothing to do with the overcrowding of the medical profession, for the situation in France is paralleled by that seen in other countries where the regulations as to military service are different. In Germany for instance, last year 1350 men received medical diplomas as against 800 ten years ago Dr Brouardel considers that social matters have most to do with the increase in the numbers of medical men. Science is becoming more appreciated by the public, newspapers give greater prominence to scientific communications, such as questions of hygiene, and even to new drugs or methods of treatment, while nearly every journal is interested in health and thinks itself capable of discussing medical subjects In addition, the medical man of to-day goes much more into general society than in former days Dr. Brouardel considers that the tendency of the middle classes to enter the medical profession is a necessary evil due to present-day social conditions and that the suppression of the right to be excused military service would not aid matters in the least. If the reasoning of Dr. Brouardel should bring about the imposition of three years' military service on medical students and so should interrupt their studies to the great detriment of their education as medical men, it will be very hard if the medical profession is allowed no compensating advantages for such sacrifices

The Alcohol Question.

The struggle against alcoholism in France is entering upon an acute stage. To the surprise of everyone M Duclaux, director of the Pasteur Institute, is heading a movement against teetotalism In interviews which have appeared in the public press and in pamphlets &c. the expense of the circulation of which has been defrayed by the syndicate of wine and spirit merchants, M. Duclaux has declared his view that alcohol is a most useful alimentary substance. In so saying he has not relied upon any recent personal investigations, but has adopted the conclusions of two American authors and has not taken into account the repeated and identical experiences of other observers. For it has been often demonstrated that if two groups of workmen in the same circumstances attack the same task, one relying upon water and the other employing alcohol the advantage gained by the latter will only be temporary, alcohol serving to bring energy into play but not being able to create it. M. Duclaux's statement as to the value of alcohol has, as might have been easy to foresee, been immediately seized upon and exploited for the good of the liquor trade, all engaged in which are now advertising their wares to the public as being *aliment indispensable pour la santé*" M. Duclaux's attitude is a reasonable one. He cannot deny the value of alcohol, and relies upon the growth of popular education to prevent the abuse of its employment. All the temperance societies—bodies which have in France a task of enormous significance, inasmuch as the country has the greatest consumption of alcohol per head—are, however, much excited by M. Duclaux's action and its results The Council of the Assistance Publique, several members of which recently formed a committee of inquiry into the practical methods for the prevention of tuberculosis has decided to placard Paris with the conclusions to which that committee came, inasmuch as they constituted mainly a warning against the dangers of alcoholism. The Prefect of the Seine and the Director of the Assistance Publique, who would be responsible for such placards, have been threatened by the syndicate of wine and spirit merchants with legal process, so that the situation is an acute one. Other circumstances are rendering it more so. Parliament will shortly be called upon to consider the position of the *bouilleurs de cru* whose privileges of distilling personally the products of their own industry are responsible for so much of the unrestrained drunkenness of France. The liquor trade are preparing to support their side with energy and money, so that M. Duclaux's excursion into the question at the present juncture is being made the subject of diverse comment by his colleagues.

Feb 2nd.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Berlin Medical Society

THE election of officers of the Berlin Medical Society took place on Jan. 14th as appointed by the by laws. Hitherto it has been a practically invariable rule to re-elect the retiring officers every year till they either resigned or died and therefore there have hardly ever been any debatable questions raised as a prelude to the elections which have, in fact, become little more than a formality This year, however, some animation was imparted to the proceedings, because the death of Professor Virchow, who had filled the office of president for many years, had left a vacancy for which two candidates were put forward by different combinations of members. The two candidates were the first vice-president, Professor von Bergmann who had acted as president since the time of the accident to Professor Virchow, and Professor Waldeyer whom the committee of the society had chosen as vice president in the same circumstances Some of the medical papers discussed the various aspects of the matter and meetings of members were even held for that purpose, as on the occasion of a contested Parliamentary election. The principal argument against Professor Waldeyer was that he, together with other members of the faculty had signed a petition to the medical chamber praying for exemption from the payment of dues to the chamber. In this petition it was said that members of the university engaged in scientific research or in the teaching of subjects not included in the practical classes of the medical curriculum were not concerned with questions bearing on the interests of medical practice and that their position differed entirely from that of the medical practitioners This petition at the time caused some indignation, because the petitioners were understood to assert that no connexion existed between the representatives of the theoretical and practical branches of medicine and the feeling of resentment thereby aroused was sufficient to deter the majority of the Medical Society (a society consisting for the greater part of medical practitioners) from voting for Professor Waldeyer. He only obtained 88 out of 386 votes, the great majority voting for the acting president, Professor von Bergmann, although his (Professor von Bergmann's) rulings in connexion with the discussions had often astonished the society The other members of the committee were re-elected.—At the same meeting Dr Katz read a paper on the Prevention of Tuberculosis He said that the results of sanatorium treatment were not so successful as was alleged , many patients who had apparently been cured became tuberculous once more and found themselves unable to work very soon after returning to their homes. The alleged cure lasted only during the stay of the patient in the sanatorium. More radical measures must be tried. The modern systems for sanatoriums entirely neglected the influence of climate , it was now an accepted opinion that sanatoriums might be situated anywhere. This opinion, however, was erroneous. It was known that in certain climates tuberculous patients benefited a good deal and he proposed to make the utmost use of this curative agent. The climate of South Africa was specially suitable for this class of patients and as Germany possessed great territories there it should be considered whether colonies of tuberculous patients could not be formed in those countries. He had already discussed the matter before the German Colonial Society and his proposal had been met with sympathy from leading colonial men.—In the discussion Professor Senator declared that although the proposals of Dr Katz to settle tuberculous patients in such distant places as South Africa were scarcely realisable owing to the expense, yet he agreed with Dr Katz's criticisms as to the success of the treatment in sanatoriums.—Professor Fränkel explained that the alleged good results were partially due to the system followed in the selection of cases which, as a rule, was made in accordance with the results of a tuberculin test, every patient in whom the tuberculin test gave a positive reaction was regarded as tuberculous, even if he had scarcely any other symptom of the disease. This class of patients, of course, recovered and in that way improved the statistical results. He had, moreover, found that the tuberculin test reacted positively in patients suffering from rheumatism, gastric troubles, and other conditions where not the least suspicion of tuberculosis existed. This test he said, did not prove anything as to the presence of tuberculosis, and he believed that many of the patients in sanatoriums were not tuberculous at all.

Professor von Esmarch's Birthday

The eightieth birthday of Professor von Esmarch was celebrated on Jan. 9th at Kiel. The former assistants of the celebrated surgeon, the German Surgical Association, the First Aid Society, the University of Kiel, the city of Kiel, and many other public bodies sent representatives, who called in the morning at Professor von Esmarch's residence to congratulate him. Many honours have been conferred on Professor von Esmarch, among others the freedom of the city of Kiel. Special numbers were issued by the *Archiv fur Chirurgie* and the *Zeitschrift fur Chirurgie* and a special work was published dealing with surgical questions and edited by Professor von Esmarch's present and former assistants. The Samaritan Association has founded an "Esmarch medal," which will be awarded by the association to persons of special merit in the first-aid and accident service. The banquet in the evening was attended by Prince Henry of Prussia, who proposed the health of Professor von Esmarch, the representatives of the various associations, and the leading men of the university and city of Kiel.

Death of Professor Saenger

Professor Max Saenger of Prague, who died there on Jan. 12th, was a German by birth and until three years ago, when he went to live in Austria, he had always held appointments in Germany. He was born in 1853 at Bayreuth, and after the completion of his medical curriculum at Wurzburg and Leipsic he become qualified in 1876. He was soon appointed an assistant in the pathological institute of Leipsic under the late Professor Wagner and also an assistant in the medical polyclinic. In 1878 he began work in gynæcology as an assistant to the late Professor Crédé; in 1881 he was recognised as *privat docent* and in 1890 he was appointed extraordinary professor. In 1887 he was at the head of a private clinic for diseases of women where he held classes which were well attended especially for post-graduate study. In 1899 he left Germany on being appointed ordinary professor at Prague. Professor Saenger's work was directed to many questions in gynæcology, both practical and theoretical. His researches on deciduoma malignum, on Cæsarean section, and on disinfection are of considerable value.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Case of Inverted Viscera.

WHILE endeavouring to localise the position of a revolver bullet by means of the Roentgen rays in a case of attempted suicide a few days ago Professor Casati of Ferrara discovered that his patient was the subject of inversion of the viscera. The revolver had been discharged in such a direction that the bullet had entered the left side of the front of the chest at the level of the third rib and had passed downwards and outwards to lodge among the muscles in the left post-axillary line. Fortunately for the patient the bullet had apparently been diverted by the rib and it is doubtful whether it actually entered the thoracic cavity. Had it done so the result in ordinary circumstances must have been fatal. It was found, however, that the heart was on the right side, some distance away from the line of fire, the liver occupying the left hypochondrium with the stomach lying to its right. Such a disposition of the internal organs is sufficiently rare, but that anyone should owe his life to the abnormality is probably unique.

Small-pox in Malta.

The Prefect of Syracuse has put in force in that port the provisions of the Maritime Sanitary Law against ships coming from Malta on account of an outbreak of small-pox in the island.

The Supposed Discovery of the Germ of Rabies.

From a second communication made to the Medical Academy of Pavia it appears that Professor Sormani cannot yet claim to have proved his thesis that the coccus discovered by him is the causal organism of rabies, since the animals inoculated with cultures of the microbe did not die from the disease nor was it possible to identify in them its characteristic anatomical lesions. He contends that his microbe differs from that described by his assistant Dr. Levy who also claims the discovery. The Academy has appointed a special commission to watch the experiments and to report the result.

The Health of Palermo.

Alarming reports having reached Rome of a severe epidemic of typhoid fever said to be raging in Palermo I have made inquiries of trustworthy persons residing there regarding their truth. The result is reassuring, for it appears that although before the October rains fell an outbreak of fever did occur it very soon died out, and that the town at the present time is in a particularly healthy state, being free even from influenza which has been prevalent in many of the northern cities of Italy during the past few weeks.

Jan. 31st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Isthmian Canal Commission.

Professor William H. Welch of Baltimore drew up and presented at the recent meeting of the American Association for the Advancement of Science the following motion which was adopted by that body:—

> Inasmuch as the construction of the Isthmian Canal is through a region in which without energetic sanitary control there is sure to be an enormous loss of human life from preventable diseases particularly from pernicious malaria and yellow fever as well as great waste of energy and of money from disabilities caused by such diseases and inasmuch as the measures for the restraint of these diseases, which have already achieved even their partial extermination in Cuba under American administration require expert knowledge based upon practical familiarity with tropical diseases experience in the application of these measures and large authority in their administration; Resolved that the American Association for the Advancement of Science begs most respectfully and earnestly to call to the attention of the President of the United States the importance of appointing as a member of the Isthmian Canal Commission a medical man possessed of the qualifications indicated. The association is convinced that the mere employment of such a sanitary expert by the commission will not be likely to secure the desired result.

The construction of the Isthmian Canal will undoubtedly be attended with much loss of life and sickness. The country through which the canal will pass is notoriously unhealthy, so that it will be necessary that a medical sanitary expert shall hold a position of authority over the workers. There will also be a great opportunity to put to the test on a large scale the value of the discoveries relating to the conveyance of malaria and yellow fever by mosquitoes. It is thought that in order to exercise the needed authority the sanitarian should himself be a member of the commission. The American medical journals have taken the matter up with the view of influencing the President to favour this plan. —The New York Academy of Medicine has petitioned the Government to appoint as a member of the Isthmian Canal Commission a medical man of proper qualifications to advise on all matters of a sanitary character. The petition states that it is well known that the previous excavations for an Isthmian canal have been attended with a large amount of illness and a heavy mortality due mainly to malaria and yellow fever, but recent discoveries as to the causes of these diseases have enabled medical officers to control their ravages to a marked degree. The success which has crowned medical efforts in Cuba in apparently abolishing yellow fever is another evidence for the belief that if proper hygienic precautions are taken at Panama and other situations along the route of the canal the death rate of the past can be greatly decreased or made to disappear. The Academy of Medicine believes that the amplest powers should be given to the medical officers in charge of the sanitation of the canal and that to attain this end a medical officer should be a member of the commission which the President of the United States is authorised to appoint to conduct the affairs of the proposed canal.

Formalin in Septicæmia

Much interest has been manifested recently in New York in some experiments made with formalin used as an antitoxic agent in septicæmia Dr Charles C Barrows of New York, the assistant of Dr Polk in the obstetrical ward of Bellevue Hospital had under his charge on Dec 25th, 1902, a negro woman who had given birth to a child eight days before. She had a temperature of 104 3° F when admitted and 24 hours after the temperature had risen to 107° The blood examined bacteriologically showed the presence of streptococci and it was undoubtedly a typical case of puerperal fever The patient, of course, was in an extremely critical position and Dr Barrows asked for permission to inject formalin solution. This request being granted an intravenous injection of 500 cubic centimetres of 1 in 5000 of formalin was made into the right arm of the woman with the effect that by the next day the temperature had fallen to 101° On the second and third day after the injection the temperature began to rise again, and on the third day it had reached 103°, when a formalin solution of the same strength was again injected, the quantity being increased to 750 cubic centimetres. The temperature has been normal ever since and the patient is to all appearances practically well. Many examinations of this woman's blood have been made since the second administration of formalin but no streptococci have been found. Formalin solution since Dr Barrow s use of it, has been administered for septicæmia following child birth in three other instances in New York hospitals. In one case it is said to have been successful but in the other two cases the results were not satisfactory In the discussion which followed the reading of a paper by Dr Barrows before the New York County Medical Society on Jan. 19th, in which he recounted the history of the patient treated by him with formalin solution at Bellevue Hospital, the view generally taken was that great hopes should not be entertained of the ultimate success of the method. Dr J W Williams of Johns Hopkins Hospital probably expressed the opinion of those present when he said ' This will prove a very great boon to suffering women if it can be substantiated but I regard it with reserve." Reference was made at the meeting by Dr Barrows to the tests with formalin made by Dr Maguire of London who has experimented on animals and on himself.

Bubonic Plague in San Francisco

There has been much uneasiness in the public mind over the repeated reports of the existence of the oriental plague in San Francisco The local authorities have constantly denied the truth of these reports and still they have been repeated and in several instances by expert medical examiners Finally, the matter has reached such an acute stage that the surgeon general of the Public Health and Marine Hospital Service Department, acting under powers recently conferred upon that service, called a conference of State health boards to meet in Washington. The conference met on Jan 19th and the surgeon general laid before the members the following communication from one of the inspectors of the Department who had been sent to San Francisco to examine the situation 87 cases have occurred in Chinatown, six sickened in other parts of the city , none proved to have originated in the country Total six whites four Japanese, and 83 Chinese since March 1900 The inspector also reported that of 22 dead rats found in China town 11 were discovered to have been infected , of 354 rats caught alive four proved to have been infected. With these facts before the conference the following declaration was unanimously agreed upon 'The present danger to California and to the United States lies primarily in the persistence during three years of a definite nidus of plague infection in that part of San Francisco known as Chinatown but the gravity of this circumstance is greatly increased by the gross neglect of official duty by the State Board of Health of California and the obstructive influence of the recent Governor of California, by the failure of the city government of San Francisco to support its city board of health, and by the obstacles opposed to the operations of the United States Public Health Service. The conference will consider the safety of the country sufficiently assured as soon as satisfied that a competent city board of health of San Francisco and a competent State board of health, in coöperation with the United States Public Health Service, will proceed under definite, harmonious, and effective laws and ordinances that they are provided with ample funds and that they are jointly and severally in the free exercise of their lawful powers." The conference also declared its belief that the habitual publication of the actual facts relative to infectious diseases and their prevention is one of the best means to minimise the dangers of an epidemic.

Jan. 29th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT)

Dental Defence Association

AT a meeting recently held in Sydney attended by about 100 dentists and presided over by Sir James Graham, it was unanimously decided that—

> It is desirable to form a dental defence association, having for its objects To render assistance to any member who may be threatened with or involved in any action at law or prosecution arising out of the practice of his profession within this State to assist in any movement which will promote fraternity amongst the members or elevate and improve the social and legal status of dentists promotion of the welfare of the dental profession of New South Wales

A committee was appointed to draw up a scheme for the formation of the association.

Sydney Medical School

At its last meeting the senate of the Sydney University adopted a report from the Faculty of Medicine recommending an amended medical curriculum. In it the work of, the present first year is somewhat curtailed, while human anatomy and practical histology (microscopical anatomy) are introduced at the end of the first year instead of the second year as at present The other changes, with two exceptions, consist in moving the subjects generally to an earlier place in the curriculum so as to allow more time in the fifth year for hospital and clinical work. Materia medica as a single separate course is omitted, while special courses upon pharmacology or the physiological action of drugs, special therapeutics and posology and prescription writing have been established In the fifth year students will be required to select two subjects from the following diseases of children, diseases of the skin, diseases of the ear, nose, and throat, special bacteriology, and special therapeutics. In lieu of the present five annual examinations there will be in future only three marking the completion of the preliminary scientific, the medical scientific, and the applied medical work respectively There will also be two term examinations—one in organic chemistry in the second year and one in general pathology in the third year At the same meeting a letter was read from Dr Thomas Fiaschi offering to deliver a voluntary course of lectures on the history of medicine to medical students It was resolved that the offer should be accepted and that Dr Fiaschi should be cordially thanked. The following examiners were appointed anatomy Dr A E Mills physiology Professor E O Stirling, C M G , pathology Dr Sydney Jamieson , materia medica, Dr A Watson Munro medicine, Dr J Macdonald Gill , surgery, Mr G T Hankins , midwifery Dr S. H. MacCulloch , gynæcology Dr Fourness Barrington clinical medicine, Dr P Sydney Jones clinical surgery Dr Fiaschi , psychological medicine, Dr Eric Sinclair , ophthalmic medicine and surgery Dr Odillo Maher , and medical jurisprudence and public health, Dr W G Armstrong

Balmain Hospital Sydney

Some friction has occurred at the Balmain Hospital, Sydney, between the paid and honorary staff. Two of the honorary surgeons have resigned. One of the trustees is stated to have asserted that the paid medical officer neglected his work of attending to out patients while attending to operations for which he received a fee. The matter is to be dealt with by the rules committee during the month

Institution for the Treatment of Alcoholism, &c

The Central Methodist Mission in Sydney has established an institution at Tempe for the treatment of alcoholism narcotism, and neurasthenia. The Medical Retreat as it is termed was formally opened by the Premier on Nov 17th. The President, in welcoming the Premier said the institution was not an inebriates' home but a medical institution conducted on scientific lines They undertook to kill the desire for alcohol and to help to restore will power The British Medical Association was aware of the formulæ and the treatment, and most of their patients were sent by medical men.

Prevention of Lead Poisoning in Mines

Regulations for the prevention of lead poisoning in mines have been published in the *New South Wales Government Gazette* The principal points are as follows. A record is to be kept by the manager of a mine of cases of lead poisoning and transmitted every month to the Chief Inspector of Mines. An ample supply of good drinking-water is to be kept at every mine, properly protected, so as to prevent contamination by dust. Standpipes and hose are to be provided to lay dust by sprinkling Every person employed in a mine must wash his hands before meals At every mine or works where lead or lead compounds are mined or manufactured bath houses and changing rooms are to be supplied The baths are to include both shower and plunge tanks. Adequate provision is to be made to prevent as far as practicable the emission of flue dust from smelter stacks Workmen employed to cleanse the flues must wear a respirator over the nose and mouth If any person shall refuse or neglect to comply with any such regulation he shall be liable to a penalty not exceeding £20, and to a further penalty not exceeding £5 for every day during which the offence is continued.

Obituary

Dr Archibald Megginson, late of Pott's Point, Sydney, died on Nov 16th He was born in Scarborough and was 47 years old He arrived in Perth, Western Australia, about 25 years ago and held the position of medical officer to the gaols Resigning this post he came to New South Wales, and after practising for a time at Merriwa settled in Sydney, where he had an extensive practice —Dr J J Miller of Brunswick, Victoria, died suddenly on Nov 26th from septic poisoning He was a native of Melbourne and a graduate of the Melbourne University Besides a general practice in Brunswick he also conducted a special practice as an ophthalmic surgeon in Melbourne He had an extensive connexion with the local friendly societies and was a great favourite in his district. He was a surgeon in the militia and was buried with military honours. Great sympathy is felt for his widow, whose brother, Dr Doolan of Tass, New South Wales, died suddenly a little time ago from appendicitis

Dec. 25th, 1902.

Obituary.

ALEXANDER THOMSON, M D, L F P S GLASG

WE have to announce the death of Dr Alexander Thomson of Dumfries on Jan 18th at the age of 70 years. An attack of influenza a few weeks ago had apparently been recovered from and he was actively engaged in professional work when he caught a chill on the 14th which was followed by an acute pleurisy ending fatally after an illness of three days Dr Thomson was a native of Shotts in Lanarkshire and studied medicine at Glasgow University After a distinguished career as a student he was appointed house surgeon to the Glasgow Royal Infirmary He was also house surgeon to the Lock Hospital there and President of the Glasgow University Medical Society In 1861 he went to Dumfries where he rapidly built up a large practice Appointed visiting physician to the Dumfries and Galloway Royal Infirmary in 1872 he resigned after two years when a vacancy occurred on the surgical staff, and to this he was appointed and continued to fill the post till two years age The directors received his resignation with regre and appointed him consulting surgeon to the hospital

For many years Dr Thomson has been recognised as the leading surgeon in the south of Scotland. He was perhaps the first country surgeon in Scotland to operate on ovarian tumours, having successfully removed one in February, 1865 As President of the Border Counties Branch of the British Medical Association in 1888, he delivered an interesting address on ovariotomy For the long period of 33 years Dr Thomson acted as medical officer of health of the burgh of Dumfries, besides holding many other important public officers By his death his medical brethren in Dumfries and a large part of the south of Scotland have lost a friend and sagacious counsellor on whom they could always rely His great experience, sound judgment, and dexterity in operating made him trusted by patients and colleagues alike. Both in hospital and private practice the loss of his always highly valued opinion will be felt for a long time to come. Dr Thomson leaves a widow and two daughters to mourn their loss

---

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr M. Lavdoffski, Professor of Histology and Embryology in the Medico Chirurgical Military Academy in St Petersburg —Dr Gessner, Professor of Midwifery in Erlangen, quite suddenly, at the age of 38 years.

Medical News.

UNIVERSITY OF CAMBRIDGE —At the Congregation on Jan. 29th the following medical degrees were conferred —

M D—A M Ware, Pembroke.
M B—G R Wilson Trinity and E S Scott Pembroke.
B C—W M. Strong Trinity E S Scott, Pembroke H C Williams, Pembroke R Butterworth Christ's E T Harris, Christ's and W W Holtzmann Christ's

A grace was carried at the same Congregation for the appointment of two additional Demonstrators of Anatomy —Dr L E. Shore, St. John's, has been appointed a University Governor of Hartley University College, Southampton.—By the death of Dr Ferrers, F R.S, on Jan. 31st and of Sir G G Stokes, F R S, on Feb 1st, the University loses two of its most distinguished heads

FOREIGN UNIVERSITY INTELLIGENCE —*Cracow* Dr J Raczynski, *privat docent* of children's diseases, has been promoted to an extraordinary professorship. Dr Majewski has been recognised as *privat-docent* of Ophthalmology —*Gratz* Dr Fritz Harmann has been recognised as *privat docent* of Psychiatry Professor Von Hacker of Innsbruck has been offered the chair of Surgery in succession to the late Professor Nicoladoni.—*Leipsic* Dr Franz B. Hofmann, *privat docent* of Physiology, and Dr Perthes, *privat docent* of Surgery, have been promoted to extraordinary professorships.—*Odessa* Dr Zabaneieff has been recognised as *privat-docent* of Surgery —*Würzburg* Dr Karl Marbe, *privat-docent* of Experimental Psychology, has been promoted to an extraordinary professorship

THE AFTER-CARE ASSOCIATION —The annual meeting of the After Care Association will be held on March 4th under the presidency of Sir William S Church, Bart., K.C B, President of the Royal College of Physicians of London The association, which renders aid to poor persons discharged as recovered from asylums for the insane, is the only charity of its kind in the United Kingdom and is deserving of more financial support than it has hitherto obtained Subscribers of not less than 5*s* per annum and persons who give a donation of not less than £2 10*s* are entitled to membership of the association, but larger annual subscriptions and donations are greatly needed. The address of the secretary is Church House, Dean's yard, Westminster, London, S W

MANCHESTER MEDICO-ETHICAL ASSOCIATION —From the fifty fifth annual report of this association we find that during the past year papers have been written on the following subjects —The Advantages of a Daily Medical Inspection of Schools, by Dr A. W W Lea, a system that was heartily approved of by the association in the interests of public health. "Professional Ethics and the Scope of the Medico-Ethical Association" was the title of a paper read by Mr F H. Westmacott, in which he pointed out that many of the advantages accruing to the profession generally were due to the efforts of this association in the earlier years of its history The following office-bearers were elected for the year 1903 —President Dr D Lloyd Roberts Vice Presidents Dr C Macfie, Dr W Thorburn, Dr. J W Hamill, and Dr J C Eames. Honorary treasurer Dr J Ferguson Honorary secretaries Mr Westmacott and Mr S Bagley Committee Mr C R C Garrard, r J J Cox, Dr W E. Sawers Scott, Dr E. Vipont own, Dr A. Stewart, Mr D Owen, Dr. T Harris, Mr W H. Garstang, Dr A. B Ritchie, and Dr G H ncashire. Auditors Dr E. Annacker and Dr J G egg

PRESENTATION TO A MEDICAL PRACTITIONER —n Jan. 20th, at Launceston, the members of a ladies' rsing class in connexion with the St. John Ambulance ssociation presented Mr William Fookes Thompson, M.D, M. Edin., with a travelling bag as a mark of appreciation his services as honorary lecturer

BRISTOL NATURALISTS' SOCIETY —The fortieth nnual meeting of this society was held at University ollege, Bristol, on Jan. 22nd, when Dr A. B Prowse gave n interesting lecture on the Wansdyke in the neighbourhood Bristol Dr Prowse was elected president for 1903, and r A. E Hudd F S A., and Mr O K Rudge, M.R C S.Eng, ere elected vice presidents.

THE LADIES' PUBLIC HEALTH SOCIETY, MANHESTER.—One of the most useful agencies in promoting e public health of the poor districts of Manchester is hat of the Ladies' Public Health Society Its work is one quietly and unostentatiously in union with the anchester and Salford Sanitary Association and under e supervision of the medical officers of Manchester nd Salford. At the annual meeting, held on Jan. 20th nder the presidency of the Lord Mayor, much ineresting information was given in the report, the rty second of the series, as to the work of the society nd the condition and habits of the poor of the disricts covered by its operations. The abnormally high eath rate among infants had led to the giving of pecial work to some of the society's visitors by the anchester and Salford medical officers of health he visitors, in the ordinary course of their duty, inquire nto the feeding, clothing, and surroundings of the babies nd explain to the mothers where mistakes have been made nd how to remedy them. They also give instruction as to he importance of cleaning floors, burning refuse, washing clothes, and the bearing of hygienic measures on the arrest or cure of consumption. The health women, as they are sometimes called, live in their districts and visit from house to house in the localities as the lady superintendents direct They carry carbolic powder explain its use, and leave it where it is accepted. They also sell soap, explain the evils of bad smells, dirt, and want of fresh air, and give hints to the mothers as to feeding and clothing the children. They write daily reports of the work done and mention the sanitary condition of the houses visited. Mothers meetings are held at which simple talks are given as to health and sanitation This sketch of the work shows that the ' visitors, ' though women of the working class, must be possessed of a good deal of intelligence and of some education, for the work requires much tact and discretion and is not over well paid for at 16s a week. The committee feels this and wishes to increase the wage but the income of the society, as is too often the case, does not equal the expenditure and so a strong appeal is made for an increase of subscriptions Last year they amounted, with donations, to £362, and the year s working left a deficit of £23. As the Lord Mayor said the income ought to be quadrupled in a city like Manchester ' The society rendered much valuable help to the sanitary committee of the corporation, whose difficulties were often almost insuperable owing to the fact that the removal of insanitary property inflicted great hardships on the poor As a rule the visitors are well received their suggestions and help being gladly accepted, and the suspicion and jealousy common enough years ago have gradually disappeared now that their motive is known—that they have come to help and not merely to spy out the barrenness of the land. The lowest death-rate in the districts worked by the society is 25 1 in the St. George s North the highest 50 9 in Angel Meadow while n Ancoats West it is 42 0 The past year was one of many calls on the charitable, but it is to be hoped hat the appeal made for more help will meet with generous response as there is much ground yet ntouched for want of means. In supporting a vote of hanks to the Lord Mayor Dr J M Rhodes mentioned a few hings not flattering to our insular vanity but which it is ell we should now and then hear He said we were too harisaical as to infant mortality In France it was only 1 per cent. greater than in England and even in Italy only 1½ per cent. higher In England and Wales 154 per 1000 die within the first 12 months. And in Denmark, instead of being 15 or 16 the death rate was under 10 per 1000 There is no likelihood of our attaining to sanitary perfection for some time to come and the fight against disease must be waged with dogged persistence.

AT the recent Seaton (Devon) urban district council bye-election Mr G E A. Evans, L.R.C P Lond., M.R C S Eng, was returned by a considerable majority

DONATIONS AND BEQUESTS —Under the will of Miss Elizabeth Turner the Derbyshire Royal Infirmary and the Derby Children s Hospital receive £300 each

MEDICAL MAGISTRATE —Mr Ralph C Bartlett, M R.C S Eng, L.R.C P Lond, has been appointed a justice of the peace for the borough of Romsey, Hants.

WESTERN DISPENSARY, BATH —The annual meeting of the subscribers of this institution was held on Jan. 26th under the presidency of the mayor The medical report stated that during the year 807 patients were treated, including 400 who were visited at their own homes The financial statement was satisfactory and showed a favourable balance of £142.

DEATH OF A CENTENARIAN —Mrs Elizabeth Alsop, of Gosden, near Guildford has died at the age of 102 years, having been born on Nov 13th, 1800, in Swallow-street, London. For upwards of 70 years she was with the late Lady Audrey Ridsdale and family and was awarded the prize offered by the late Duchess of Teck for the longest record of service with any one family

ROYAL INSTITUTION —The Friday evening discourse at the Royal Institution on Jan 30th was delivered by Professor W E. Dalby, the subject being Vibration Problems in Engineering Science. Illustrations were taken chiefly from locomotive engines on railways and from the engines of steamships Many fine models of machinery in motion were shown.—A general monthly meeting of the members of the Royal Institution was held on Feb 2nd, Sir James Crichton Browne, treasurer and vice-president, being in the chair The following were elected members: Dr Louisa Garrett Anderson, Dr Henry T Böttinger, Mr W Child, Mrs. Ionides Miss Lea Smith, Sir Frederick Treves, Bart., and Mr W Whitehead.

NATIONAL DENTAL HOSPITAL.—The annual general meeting of the governors and supporters of the above institution was held at the hospital on Jan. 27th, Mr F Cavendish Bentinck presiding Among those present were Mr Alfred Farquhar, the treasurer, Captain Maxwell Earle, D S O, Mr W Ward Cook Mr F Canton, Mr. Alfred Smith, Mr Charles W Glassington, and Mr Sidney Spokes, Dean of the College The committee reported an increase over the total of last year in the number of patients treated of 2682, as well as a consequent general addition to the amount of the various kinds of work performed. It also had the gratification of stating that the new regulations which came into force on Oct 1st were working satisfactorily and promised a still greater improvement in the future. The committee regretted to have to call attention to the deficit as shown on the balance sheet, of £863, of which debt £296 were incurred in 1901 and £566 in 1902, and ventured to observe that it was not possible to execute such a largely increased amount of work without additional expense. The committee begged all supporters of the hospital to use their best endeavours to obtain further subscribers in aid of the work, the number of annual subscriptions being quite disproportionate to the growing requirements of the institution and the committee being very anxious that the work should not have to be curtailed in consequence of deficient income.

Notes, Short Comments, and Answers to Correspondents.

THE PRESCRIBING QUACK

A CORRESPONDENT has forwarded to us a card in an envelope which was left at his house. The envelope is addressed in print To the Lady of the house The card inside a four page one, states on its front page that it is A private note from Francis E Bustard (M P S), Cash Price Chemist Medical Herbalist &c 663 Seven Sisters road South Tottenham. On pages 2 and 3 is the following —

> MADAM —A word to the wise is sufficient In all cases of Indigestion Persistent or Recurrent Headaches Habitual Constipation Anæmia Bad Legs and other forms of Female Weakness or Irregularity prompt attention is the only method of averting serious trouble
>
> If you present this Card at my counter you will be shown at once into my private consulting room I charge *nothing for advice* and I WILL HELP YOU IF I CAN At any rate a few minutes strictly private conversation with a fully qualified Chemist will cost you nothing and *a few herbs a box of pills or a bottle of* medicine IF TAKEN IN TIME may save you a great deal of suffering and expense I am Madam
>
> At your Service
>
> FRANCIS E BUSTARD (M.P S)

On page 4 we notice that Mr Bustard sells No 4 Special Female Pills Ladies Occasional Mixture Female Corrective Herbs and Female Injection Powder" From *these items* and *from* the references to ' Female Weakness or Irregularity on page 2 of the card it is quite easy to see what manner of trade Mr Bustard carries *on* and *we commend his business not only* to the notice of the Pharmaceutical Society but also to that of the police.

WANTED—SUGGESTIONS FOR TREATMENT

To the Editors of THE LANCET

SIRS —Will one of your readers kindly advise what treatment should be adopted in the case of a man about 42 years of age whose spleen is five times larger than normal At present he is not feeling in first class health but is suffering no inconvenience from the enlargement. Would it be advisable to remove the spleen? Has any other treatment been successful in similar cases? Have the Roentgen rays been used with success in such a case? The following is the result of an analysis of the blood:—Macroscopic appearance pale fibrin decreased coagulation slow *specific gravity* 1051 *hæmoglobin* 52 *per cent erythrocytes* 2,812 800 leucocytes 8933 ratio of leucocytes to erythrocytes 1—314 *Erythrocytes* —Normocytes pale microcytes many present macrocytes medium number poikilocytes considerable number schistocytes absent normoblasts 20 to the cubic millimetre microblasts absent megaloblasts absent blood plates decreased *Leucocytes* —Lymphocytes (small) 24·25 per cent. lymphocytes (large) 10 75 per cent polymorphonuclear neutrophiles 64·50 per cent eosinophiles 25 per cent myelocytes none basophiles 25 per cent. myelocytic eosinophiles none. *Parasites* —Plasmodium malariæ, none

I am, Sirs yours faithfully

Feb 2nd CLARKDON

THE SPRING AXLE BICYCLE

MR. S HALL of 56 St Augustine's-road Camden-square *London,* N W asks us to call attention to an invention which *consists* of helical springs having two and a half inches vertical play *contained in tubular plungers connected to* and forming part of the fork and frame of a bicycle and fitted to slide in tubes or cylinders rigidly fixed *to* the axles the upper ends of the springs bearing on the under side of capped nuts at the top of the plungers and their lower ends on the upper edge of small plates fixed across the cylinders long longitudinal slots in the plungers permitting the sliding action under the play of the springs. In the lower part of the plungers are similar but shorter springs the upper ends of which abut on the under edge of the small plates their duty being to prevent the plates coming in contact with the bottom of the slots when the springs proper cease *to* be *in compression Among* the advantages which the inventor claims for the spring axle" are reduction of wear and tear throughout *the machine* and greater comfort to the rider Theoretically the spring axle" bicycle seems to possess the advantages which its inventor claims for it but time only can prove its merits It should be mentioned that *the invention can be applied to motor cars* as well as to cycles

MOLASSES AS A "CURE FOR CANCER."

A MEDICAL man in Kent has sent us a cutting from a Queensland newspaper which states that two men in that colony claim to have been cured of cancer by taking about a tablespoonful of molasses four or five times a day In one of them the seat of the trouble was at the root of the tongue and quite disappeared after ten days treatment. The other patient suffered from the same complaint" in the stomach and for him a three months course of the remedy was required after which he was able to resume his work as a labourer on a wharf Each of these individuals seems to have been unconsciously neglectful of his duty both to himself and to his fellow men for he has omitted to supply the proofs of his case necessary to raise him to the position of a historical personage and (which is worse) he has authorised the publication of a claim to have been cured of cancer" which may delude some genuine sufferers and tantalise them by raising hopes foredoomed to disappointment

'THE GOLFER'S DIARY AND MATCH BOOK"

WE have received for review from Messrs John Walker and Co Limited of Farringdon House E C several specimens of the 'Golfer's Diary and Match Book which has been compiled for them by Mr T B Earle The immense popularity which golf now enjoys among men of all ages makes the game a factor in our national health so that perhaps to notice a pocket book devised for the use of the golf player is not going so far outside our proper sphere as it may appear to some to be As citizens it might be our duty to point out that far too much time is spent by many men in pursuit of this engrossing game but as medical men we are bound to weigh against this fact the other fact that in golf thousands find a form of exercise and relaxation which is their only safeguard against physical breakdown We have given the diaries to a member of our staff an enthusiastic golfer who has reported of them to us very favourably In enlarging on the merits of the game to us, and in an exposition which he insisted on making of certain of the procedures of golf etiquette he became technical to the point of incomprehensibility but his commendation of the diaries was perfectly clear He considered that if every regular golfer carried such a book about with him the opportunity of immediately referring to the rules would obviate many annoying disputes while a regular record of the year's performances would instil hope into some breasts and humility in others—his opinion apparently being that his fellow golfers are, as a rule, either unnecessarily depressed or unduly bumptious The diaries are supplied in various covers at prices ranging from 1s to 10s the contents being renewable each year for 1s

CURIOSITIES OF THE MEDICAL DIRECTORY

A CORRESPONDENT, encouraged we fear by the lapse from seriousness of a recent annotation in our columns writes to us as follows: 'It appears that in none of the sections London Provincial Wales &c., is there the name of any medical man beginning with X, which, perhaps, is not x traordinary In Wales there is no U which is un U-sual and there is no Y Z there which is too general a statement to be libellous In Scotland there is no Q which is certainly Q rious. In Ireland there is no Z which is Y the list finishes with a Y As for the dentists they have only got one I amongst them" We publish our correspondent's note but in doing so we warn him that a repetition of such facetiousness will shake our confidence in his ability to discharge his onerous and responsible duties.

MADAME SPITZNER'S GREAT MUSEUM

WE learn that this exhibition to which we called attention in THE LANCET of Jan 24th was raided by the police on Feb 4th The proprietress and other persons connected with the show were arrested and the place was closed.

THE TESTIMONIALS TO ODOL

A CORRESPONDENT points out to us that among the testimonials to the value of Odol which have reached him in a circular is one from Dr Leonard Wilde who has been dead he says two years We believe Odol to be a new preparation so that it is difficult to see how a physician who has been dead two years could have given a good report of it In view of recent communications to the medical press we think that the proprietors of Odol should be more careful about their circular advertisements

KEEN'S OPERATION IN TORTICOLLIS

To the Editors of THE LANCET

SIRS —I should be obliged if some one could tell me (through your correspondence columns) if Keen's operation should be done *on both sides* in a case of spasmodic torticollis in which the (clonic) spasm is now confined to the left side whereas 18 months ago it was found in the right side only having continued there for more than a year

Does this change indicate that the cells in the anterior cornua on the right side are now exhausted and therefore that a unilateral operation will be sufficient? I am Sirs yours faithfully

Jan. 27th 1903 A. C R.

A REVOLVER FOR 7s 9*d*

THE origin of the cheap weapons used by mischievous boys criminals, and persons mentally deranged is not always traceable At Bow street police court however evidence was given recently in the case of two burglars apprehended with revolvers upon them that they bought their pistols for 7s 9*d* each from Messrs Gamage and Co in Holborn The price and the ease with which such dangerous articles can be bought by anyone are the points to which attention should be directed The number of suicides by shooting that have occurred lately has been too great for attention to be drawn to individual cases The danger arising from the pistol traffic to public personages has also been emphasised by the incident which has taken place in Spain and by the trial at the Old Bailey of the lunatic who called at the German Embassy and failing to obtain an audience from any official within, shot a cab horse outside. No comment seems to be needed upon cases such as this perhaps when a valuable life has been sacrificed something will be done.

F S H—As a rule British diplomas and degrees entitle medical men to practise in Canada without any examination A licence must be obtained from the provincial medical boards and certain fees have to be paid for the registration of qualifications Complete information on the subject is contained in the 'Professional Handbook," No 11, issued by the Emigrants Information Office, 31, Broadway, Westminster S W Our correspondent might also apply to the same office for information with regard to his second question

P P (M.B) and Y D (M D)—We have published many protests in the sense suggested by our correspondents but with little effect. It is disgraceful and a terrible commentary on modern morals that papers with a wide circulation should spread such lies because advertisers have paid for their insertion With one of these articles—the one that removes all obstructions —we have dealt in our series of articles entitled 'Quacks and Abortion" (THE LANCET, June 24th, 1899 p 1739)

Inquirer—It would have been better to avoid the situation and we think that the town councillor would have been well advised to abstain from voting The election of his assistant is perfectly legal and public opinion, if nothing else may probably be trusted to make him a just representative of authority in spite of his personal relations with the medical officer of health

Lusitania—For a foreign medical man who desires to exercise his profession in Portugal it is necessary to pass an examination held by the Faculty of Medicine of Lisbon Coimbra, or Oporto He will then be able to practise in Portugal and also in Portuguese colonies. The total fees, including examination and registration, amount to about £60

General Practitioner is advised not to enter into such an arrangement. He will make himself the servant of lay employers The present system is preferable As far as we can see the emoluments are as large and every bit as certain, while the independence should be greatly prized

B B—We do not know any book that gives satisfactory information upon the point It will be best for our correspondent to seek the advice of an experienced friend on the general question If any particular points arise a medical man might be consulted.

T K C is thanked for his letter and its inclosure. We do not think that the official attitude is worth criticising it is so manifestly silly and opinionated

M D (Captain I.M S)—Our attention has already been drawn to the matter, but we believe the lady to have been the victim of injudicious friends

L. N—No

Medical Diary for the ensuing Week.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Bidwell: Plaster of Paris Splints.

UNIVERSITY OF LONDON (Physiological Laboratory).—5 P.M. Dr. W. D. Halliburton: On the Chemistry of Muscle and Nerve. (Lecture on Advanced Physiology.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Sir Wm. Gowers: Degenerative Diseases.

WEDNESDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Clarke: Clinique. (Surgical.) 5.15 P.M. Dr. C. O. Hawthorne: The Visual Field in Chronic Nervous Disease. I.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. D. Robinson: Pelvic Pain.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Discussion on the Present Shortage of Water available for Supply (opened by Mr. W. Whitaker). General discussion is invited.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. J. J. Perkins: The Abdominal Manifestations of Thoracic Disease.

THURSDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson, jun.: Clinique. (Surgical.) 5.15 P.M. Dr. C. O. Hawthorne: The Visual Field in Chronic Nervous Disease. II.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Treatment of Some Injuries and Emergencies.

UNIVERSITY OF LONDON (Physiological Laboratory).—5 P.M. Dr. T. G. Brodie: On the Circulation. (Lecture on Advanced Physiology.)

CHARING CROSS HOSPITAL.—4 P.M. Dr. A. Routh: Gynæcological Lecture. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Voelcker: The Sequelæ of Diphtheria.

FRIDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. R. Lake: Clinique. (Throat.) 5.15 P.M. Dr. H. Tilley: Purulent Nasal Discharges. II.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. E. Jones: States of Mental Depression—Melancholia, Katatonia.

UNIVERSITY OF LONDON (Physiological Laboratory).—5 P.M. Dr. A. D. Waller: On the Action of Anæsthetics and Narcotics. (Lecture on Advanced Physiology.)

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1902, which was completed with the issue of Dec. 27th, and the Title-page to the Volume, were given in THE LANCET of Jan. 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

The Harveian Lectures

ON

FIBROIDS OF THE UTERUS AND ITS LIGAMENTS CONSIDERED FROM A CLINICAL AND SURGICAL STANDPOINT

Delivered before the Harveian Society of London on Nov 6th, 13th, and 20th, 1902,

BY ALBAN H G DORAN, F R C S ENG,
SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN MARYLEBONE ROAD N W

LECTURE II.[1]

Delivered on Nov 13th, 1902

THE TREATMENT OF THE OVARIES IN HYSTERECTOMY FOR FIBROID

MR. PRESIDENT AND GENTLEMEN,—Mr J Bland Sutton, fortified by Dr G Crewdson Thomas's valuable statistics,[2] maintains that when more or less of the ovaries is left the catamenia are not, as a rule, suppressed, whilst in cases when they stop the menopause symptoms are far less severe than when the ovaries are entirely extirpated But certain authorities hold that other conditions are necessary besides leaving ovarian tissue, to ward off a severe menopause, whilst there may be distinct evil effects due to leaving ovaries behind On the strength of experience on which I shall shortly dwell at some length, I maintain that this conservative operation entails benefits, but that those benefits have been over estimated. There is no reliable homology between the removal of normal ovaries with a fibroid uterus and double ovariotomy for ovarian tumours We know nothing about the influence which ovarian new growths may exert on the menstrual phenomena before they are removed. As a rule the period is quite unaffected in double cystic disease, whilst some malignant tumours are associated with amenorrhœa which sets in long before cachexia I find that in a series of double dermoids in my own practice flushings, &c., were very rare, though the suppression of the period was rapid and complete after ovariotomy Yet in my first case (1882) when the patient was 32 years of age, and where there could be no doubt about the complete extirpation of both tumours, there were troublesome flushings for nearly 10 years No period occurred after the operation. Again, when enucleation is necessary it is very possible that a piece of healthy ovarian tissue may be left in the ovarian ligament, as in a case of my own where the patient bore a child two years after a second ovariotomy[3] Martin's tables of his double ovariotomies[4] are instructive but of no value for our present purpose for reasons just suggested He makes no note of severe menopause symptoms I must remark, however, that he registers one case where cancer of the cervix occurred in a patient from whom he had removed two ovarian tumours of an innocent type. We may bear this in mind when considering cancer of the stump after hysterectomy

If we cannot, in relation to our present purpose, dwell profitably on the effects of double ovariotomy for tumours on menstruation, still less need we pause to consider the results of oöphorectomy for inflammatory diseases of the appendages or for checking the growth of a fibroid. In hysterectomy for fibroid, as was explained in the first lecture, the extirpation of the ovaries is nearly always easy and thorough when so desired. After oöphorectomy for any purpose he is bold who can ever feel certain that no ovarian tissue has been left behind. So I will say no more concerning the loss of both ovaries save so far as it regards hysterectomy for fibroids. I shall have to make use of the term "cervical menstruation," by which a periodical flow of blood from the stump of the cervix after hysterectomy is understood. The term is clearly convenient, but the precise nature of cervical menstruation remains obscure Bleeding from the stump of the cervix may be due in some cases to a polypus or to an interstitial fibroid in its walls, but then the flow is not necessarily periodical and regular and not associated with molimen, this was the case in one instance which I shall mention when speaking of bleeding in relation to diagnosis of uterine fibroids. It is certain that true cervical menstruation is not caused by overlooked polypi and interstitial growths

There are four questions to be solved in respect to the treatment of the ovaries in hysterectomy for fibroid We must firstly find out if the period always ceases after hysterectomy with removal of both ovaries, secondly, if their removal really involves very bad menopause symptoms, thirdly, if, when more or less be left of the ovaries, the period will continue regular, and lastly, if this preservation of the ovaries be wholly beneficial In order to throw light on these four questions I have carefully scrutinised 44 cases in my own operative practice between March, 1897, and July, 1901, rejecting several more where the after history is too short or otherwise unreliable. The cases may be grouped under three classes Class I., both ovaries removed, includes 25 cases, Class II, one ovary or part of one ovary not removed, 17 cases, and Class III., neither ovary removed, two cases. As I have found that the worst features of fibroid prevail between 40 and 45 years of age I have operated most frequently on patients at about that age (24 out of the 44 cases), leaving 12 whom I may call "young" and eight "old" One case, 50 years old, is included as still menstruating, all older cases are rejected

In considering the first question let us see if removal of both ovaries necessarily results either in immediate or at least in speedy and absolute suppression of the menstrual function. In my 25 cases where both ovaries were entirely removed no show of blood, with more or less molimen, occurred after convalescence in any save in four distinct exceptions. In one of these it appeared once six months after operation, in one it reappeared and still occurred, though irregularly, 13 months after operation, in one it was maintained two years, and in the fourth for two years and seven months though clearly beginning to cease. I have sketches of the parts removed in two of these cases and they show that the ovaries came away entire whilst the infundibulo-pelvic ligament was tied and divided well outside each ovary I have already explained that it is almost as difficult not to take away the ovaries entire in a hysterectomy as it is hard to extirpate them entirely when the fibroid uterus is left behind Thus suppression of the menses is not always immediate and absolute, for cervical menstruation *whatever that may be*, continues in some cases It always tends to cease, but it may do so, as will be presently shown, when one or even both ovaries are saved.

The second question is closely associated with the first. Does removal of both ovaries necessarily cause very bad menopause symptoms? In 21 cases, those where the menopause was complete after the removal of both ovaries, there were no symptoms whatever in seven, mild and infrequent flushings in seven, and severe symptoms in seven. In six of the last seven there were simply the usual subjective evidences of the change of life severe enough to give discomfort The seventh developed symptoms of persecutory mania a few months after the operation, they soon subsided. Her relatives then informed me, for the first time, that she had already suffered from persecutory mania In another case, of which I lost sight within four months after the operation, so that she is not included in the series, the patient an eccentric single woman aged 42 years, left home with her nurse after convalescence and has refused ever since to communicate with her relatives but the operation was not followed by shock and there is no reason to believe that she became insane. I find that Dr Crewdson Thomas registers two cases of mental symptoms, both in patients of unstable mind before the operation. But post-operative insanity is well known in general surgery Most of us have seen the specimen in the Museum of the Royal College of Surgeons of England of two cysts removed from the breast of a woman aged 51 years, with its history "The patient became insane soon after the operation."[5] Again, coincidence must be taken into account as well as other considerations in any example of insanity associated not only with operations but also with an operable disease where nothing has been done. I had two instructive cases in my wards at the Samaritan Hospital a few years ago One was a hysterectomy for fibroid where I used the serre nœud. The patient was violently excited on the second and third days, but ultimately calmed down and got perfectly well At the same time there was a middle aged woman in another ward with an ovarian tumour, probably dermoid, and to all outward appearances a simple case. On the day before that which had been fixed for the ovariotomy this patient had a violent attack of acute mania. She was removed and died a few days later with no symptoms attributable to the tumour Had I operated on the day before the attack and had the same fatal complication followed the ovariotomy I certainly should have charged the operation with causing the mania and I must have registered the case as a death *after*—always understood as *from*—ovariotomy

---

[1] Lecture I was published in THE LANCET of Feb 7th, 1903 p. 350

[2] The After histories of 100 Cases of Supravaginal Hysterectomy for Fibroids, THE LANCET Feb 1st 1902, p. 294

[3] Pregnancy after Removal of both Ovaries for Cystic Tumour Transactions of the Obstetrical Society vol. xliv (1902) p 231.

[4] Die Krankheiten der Eierstöcke und Nebeneierstöcke, 1899 p. 907

[5] Museum of the Royal College of Surgeons of England, Pathological Series No. 4760.

The above cases show that we must be careful about throwing the blame on the operation and not too ready to attribute mental complications to the manner in which the ovaries are treated I do not deny that removal of the fibroid uterus seems to have a specially bad influence on a patient liable to mental disease. I know of two cases of acute mania after hysterectomy with application of the serre nœud one was reported by Dr Herbert Spencer at the Manchester meeting of the British Medical Association. I suppose that psychologists would include my own case just mentioned. The serre nœud always gave great pain, a fact which should be taken into account

We must now return to other points of interest in association with my 21 cases of hysterectomy where the menopause was complete after the removal of both ovaries Marked *corpulence*, developing rapidly, was noted in two cases, in one the patient was 30 years of age and in the other 50 years of age, but still menstruating Yet sudden accession of stoutness was also observed in a patient aged 40 years where one ovary was saved In respect to *age*, Dr Crewdson Thomas lays stress on youth in relation to the severity of the artificial menopause According to his tables "the younger the patient who has her ovaries removed the more severe will be her artificial menopause." Out of my 25 cases where both ovaries were removed four were under 40 years of age and of these one had severe symptoms, two had mild, and one had no symptoms at all, but these numbers are too small to be trustworthy Lastly, as in seven out of 25 cases of removal of the ovaries with the uterus, or 28 per cent., there were marked menopause symptoms I think that it is best to leave one or both ovaries if healthy, the more so as this conservative practice involves a far smaller wound on each side of the cervix But at the same time my experience shows that retention of the ovaries is not a matter of supreme importance and I find, as will be shown, that it does not guarantee the patient against a severe menopause. Hence I never scruple to remove the ovaries when there is the least suspicion of ovarian tumour or when there is marked inflammatory disease of the appendages

The third question is whether the period remains regular after hysterectomy when more or less is left of the ovaries.[6] In two out of the 44 cases I removed neither ovary One patient was 24 years of age, her period continued regular over two years after the operation The other was 45 years of age, I removed a tumour over 12 pounds in weight The period occurred three times after the operation and then ceased altogether This may have been a natural menopause In 17 of the 44 cases I left one ovary or in one case only a piece of one ovary In only four did the period persist, strange to say, one of these patients is phthisical, yet she remains regular over two years after the operation. In four there was irregular "show" whilst in the remaining nine, or nearly 53 per cent of the 17 cases, the period did not appear after operation, and in five out of these nine the menopause was distinctly severe. One of the five was 36 years old, all the others were between 40 and 45 years of age.

There is another factor, however, to be considered besides the preservation of the ovaries—that is, the preservation of a portion of the tissue of the uterus above the cervix as well. Abel and Zweifel[7] declare that it must be saved, and, what is more, it is a bit of the uterine mucosa above the os internum that must be left, else a severe menopause will come on at least within three years Dr Crewdson Thomas kindly informs me that he "was unable to get any evidence to support this view" American authorities ignore Abel Zweifel principles, for Kelly directs that the uterus be divided "in its cervical portion at a point just above the vaginal junction",[8] and Noble[9] considers that in Europe too much cervix is left. The results of panhysterectomy where no cervix is left have not been accurately recorded My own experience, to a certain extent, supports the Abel Zweifel theory For in six of the cases where the period was completely suppressed though one ovary was not removed I had cut the stump short entirely below the os internum. Persistence of the period was noted in three cases where one ovary was left and uterine tissue above the cervix was included in the flaps. But it also persisted in a fourth case where the stump was entirely cervical, whilst, on the other hand it was suppressed entirely in three cases where the flaps included uterine tissue and at the same time one ovary was left behind We must beware of making uterine flaps to accommodate ourselves to a theory which is not thoroughly proved by experience, and which, if true, can only confer a benefit of not very high value The practice is not without danger Large fleshy flaps are liable to slough, especially when the patient is reduced by anæmia. I lost two cases in this manner, whilst in some included in this series I observed symptoms during convalescence which gave me anxiety and other operators have informed me that their experience is similar

We have now to consider the fourth question · Is the practice of leaving the ovaries or sparing one ovary wholly beneficial? has it any disadvantages? and may it not be dangerous in certain circumstances? How far removal or saving of the ovaries influences the possibility of cancer developing in the stump we cannot say, but this matter will be considered presently Cancer of the stump seems unknown in British practice There can be no doubt, however, that the appendages when retained occasionally inflame Both Fritsch and myself have observed perimetritis after hysterectomy I suspect that this complication is usually due, not to inflammation of an ovary, but to an unhealthy tube The tubal canal after ligature and division lies exposed at the point where the tube has been cut through. Not only immediate, but also distant, inflammation might follow Dr G G Bantock recently removed a pyosalpinx which had developed seven years after hysterectomy for fibroid I always sacrifice appendages which seem unhealthy in order to avoid these undesirable after results, and I will indicate the precautions necessary in dealing with diseased tubes at a hysterectomy

The most serious objection to leaving the ovaries is the possibility of their becoming the seat of tumour I will presently speak of Littauer's case of blood cysts in an ovary removed about nine months after panhysterectomy It is not clear that the tumour in this case was a true new growth, it was small and seemed to be made up of dropsical follicles full of blood and perhaps it would have atrophied if left alone But Dr Bantock removed in July, 1895, the uterus of a woman, aged 46 years, for cystic degeneration of the cervix, operating through the vagina. Both ovaries appeared to be perfectly healthy Six years later the same operator removed from the patient an ovarian tumour weighing five and three quarter pounds, it had strong pelvic adhesions Thus we must remember that ovaries left behind may become subject to tumour That this is not in itself sufficient reason for removing them with the uterus, I admit, for experience has shown that the development of an ovarian tumour after hysterectomy is very rare. In some cases where they have been detected after that operation they might have existed already and been overlooked by the surgeon. The specimen which I exhibit shows that a small cystic tumour of the ovary might be overlooked by a too speedy operator In this instance a fibroid blocked the pelvis. I tied off the broad ligaments close to the uterine cornua and pushed them down at the beginning of the operation The only portion of this ovary which was in sight seemed healthy At the end of the operation I carefully inspected the relations of the stump and then I detected this ovary converted as you see into a cyst of some size concealed behind a coil of adherent intestine. It is easy to understand how a small tumour of this kind might be overlooked, especially in a case where the operator thinks it advisable to close the abdomen speedily The answer to the fourth question is that leaving the ovaries may entail danger, but experience shows that the risk is not great.

---

[6] Howard Kelly (Operative Gynæcology, vol ii. p 370) advises that both ovaries be left in a subject under 40 years of age although menstruation ceases He finds that a severe menopause is thus avoided

[7] Referate über die Behandlung der Myome Centralblatt für Gynäkologie 1899 p 616

[8] Operative Gynæcology vol ii p 370 Let it be noted that Kelly finds that menstruation ceases though both ovaries be left (vide supra)

[9] Personal Observations concerning the Present Status of Gynæcology in Europe American Medicine, Oct. 12th 1901

In respect to the effect of removing or leaving the ovaries the question of previous hæmorrhage ought to be taken into account. With our present knowledge, however, I cannot see how we can draw any correct conclusions. Some women tolerate very little hæmorrhage, others seem almost the better for free bleeding going on for years. The cause of the menorrhagia is certainly not identical in all cases. Sudden cessation of the free bleeding of necessity occurs directly after hysterectomy, then there may or may not be some constitutional disturbance, but whether that disturbance be chiefly due to the sudden cessation of hæmorrhage or to the treatment of the ovaries we cannot determine with precision As far as I can make out the patients reduced by long and severe hæmorrhages suffer nothing at all by their cessation whether the ovaries be left or removed. Dr Crewdson Thomas, I find does not tabulate "hæmorrhage" in his series I fear that this dissertation on the ovaries has been very tedious I have earnestly endeavoured to get at the truth and therefore I did not set to work at these researches with intent to prove that it is best to remove the ovaries, or that it is best to leave them or that it matters little how we treat them. My results seem somewhat indefinite, but the indefinite may be the truth especially where there are so many complex factors to be taken into consideration

FAMILY HISTORY OF FIBROIDS.

According to my own experience a family history of fibroids is more interesting than important I find, like others, that a strong history is to be detected on inquiry in some families. In one remarkable instance the mother underwent hysterectomy for fibroid, while three daughters are subject to fibroid disease, in two it has remained stationary for several years, while in the third the tumour suddenly increased and I recently removed it The mother's sister died from uterine cancer and so did a fourth daughter, whilst there remains a fifth from whom a fibroid polypus was removed , there is at present a small growth in the cervix. This solitary family history is of no value for general considerations about the relations of fibroid to carcinoma. I must note one family history which I mentioned in opening the discussion on the Natural History of Fibroids at the Ipswich meeting of the British Medical Association in 1900 There were three sisters, all single, and all between the ages of 30 and 40 years In all the fibroid was interstitial or partly subserous and there was but moderate menorrhagia In two the tumour suddenly increased in size and I operated, with good results. In the third the tumour was the largest of the three six years ago , it remained stationary for four years and recently seems to have grown smaller and harder Hence family history is not a sound guide to prognosis and treatment

BLEEDING IN RELATION TO DIAGNOSIS OF UTERINE FIBROIDS.

Clinical experience has taught and proved that menorrhagia and intermenstrual hæmorrhage associated with a uterine tumour are strong evidence should there be good reason to exclude cancer, that the new growth is a fibroid A fibroid wholly subperitoneal does not cause hæmorrhage, whilst in the submucous variety bleeding is rarely if ever absent, and a little polypus is as a rule, a source of relatively free hæmorrhage The presence of a polypus or of submucous growths often accounts for menorrhagia when a large subserous fibroid is present. For evident reasons it is easy to overlook a polypus in many cases of uterine fibroid. In the days when ovaries were freely removed with a view to check the growth and bleeding of fibroids an overlooked polypus sometimes maintained hæmorrhage The same after-history was not rare when the serre-nœud was applied in hysterectomy for the cervix could not then be thoroughly explored, as is the case when the body is amputated by newer methods In 1892 I had under my care a woman, aged 47 years suffering from a cystic uterine fibroid of large dimensions[10] I noted before operation "small pedunculated polypus of cervix." I removed the tumour with tubes and ovaries entire and applied the serre-nœud to the cervix without troubling about the polypus. For more than a year after the operation there was occasional discharge of blood from the os externum. Before the operation there had been no menstruation for six months

In association with polypus the diagnosis of another tumour may be obscured A polypus may be overlooked in a case of ovarian tumour closely connected with the uterus , then its bleeding may induce us to mistake the ovarian tumour for a cystic or solid fibroid of the uterus On the other hand, a uterine polypus does not always cause bleeding

One case in my experience where bleeding obscured diagnosis had a very instructive history In the autumn of 1886 a woman, aged 39 years, was referred to me by Sir Spencer Wells. She had noticed for eight years a tumour which had increased in size very slowly We were of opinion that it might be an ovarian growth, but that if uterine removal would be more dangerous than leaving it alone The period was moderate In September, 1886, I cautiously explored the tumour through a short incision. It had a dull red capsule and, as far as could be made out by digital exploration, was absolutely incorporated with the uterus. In those days hysterectomy for large burrowing fibroids was attended with high mortality and we had in our minds Keith's observations about his first hysterectomy where a cystic fibroid was taken for an ovarian cyst.[11] I thought it best not to attempt the removal of the tumour I kept the patient under close observation for many years as I was not quite certain about my own diagnosis The girth of the abdomen increased until 1890 and then slowly decreased till the menopause in 1900 Dr C H J Lockyer, who saw her in the out-patient department of the Samaritan Hospital, noted that the menopause was preceded by severe hæmorrhage which lasted for six months Then the tumour began to increase rapidly in size, so in November, 1901 I operated once more. The tumour was a burrowing multilocular cyst of the left ovary so closely associated with the back of the uterus that I removed that organ as well, leaving the right ovary Strange to say, though I did so and though the menopause had been passed the patient had fresh menopause symptoms after convalescence. Dr Lockyer carefully examined the parts removed and he found in the uterus a small polypus. This growth was in all probability the cause of the hæmorrhage , there had been no menorrhagia previously to the menopause though the tumour had existed for years but the bleeding naturally suggested that the earlier diagnosis of uterine fibroid was correct.

Quite recently I removed a large ovarian cyst from a woman aged 66 years , she had suffered from hæmorrhages suggesting cancer, but a polypus was detected and removed Diagnosis was easy in this case but would have been otherwise had the cyst burrowed and come into very close connexion with the uterus After all, we are all aware that a polypus causes bleeding and therefore, if overlooked when associated with a tumour which does not set up menorrhagia no wonder we are puzzled. Dilatation of the cervix of a fibroid uterus in order to search for polypi is a dangerous procedure. But it must be remembered, I repeat, that a polypus sometimes does not cause bleeding

I operated last year on a single woman aged 46 years, who was suffering from a rapidly growing fibroid. The period was regular and always moderate and there was never any intermenstrual hæmorrhage. The tumour was a spherical myoma in the anterior wall of the uterus, undergoing mucoid degeneration. Dr Lockyer, in examining the parts removed, found a pedunculated polypus one inch long in the uterine cavity, attached near the fundus There was also a submucous polypus bigger than a pea In short, there ought to have been hæmorrhage[12] if the fibroid had known how to conform to the most elementary text book

I have already referred to a case where a polypus in the stump of the cervix caused hæmorrhage. In a case reported by Doléris[13] the menorrhagia for which the fibroid had been removed only increased, until a year later when he operated once more and dissected a small interstitial fibroid out of the substance of the stump , the bleeding then ceased We all know what a bleeding fibroid is and we are all acquainted with fibroids that never bleed. I need not dwell on them as I have determined to limit my remarks to exceptional conditions in relation to hæmorrhage or its absence as a symptom

ASCITES AND UTERINE FIBROID

For some reason by no means evident ascites is rarely found in association with any form of uterine fibroid. In Keith's case[14] the complication developed after a fall, when the tumour was struck against a low railing Butler Smythe s patient was knocked down by a cart and much bruised on the abdomen, thighs, legs, and arms[15] Symptoms of peritonitis followed, 18 pints of ascitic fluid were withdrawn three months after the accident After four more tappings the fibroid was successfully removed The tumour consisted of two subserous growths and there were numerous omental and intestinal adhesions Thus in both these cases the free fluid collected in the abdomen as the result of an injury to a patient suffering from fibroid and not as a direct result of the tumour Blows on the abdomen injuring a fibroid may set up other kinds of local mischief An elderly patient of mine subject to this kind of tumour fell down a flight of stone steps and struck her abdomen. A soft mass developed in the interior part of the tumour with symptoms of peritonitis An ugly swelling formed, the skin was glossy and injected, and I feared sarcomatous degeneration I incised the swelling, which proved to be a suppurating hæmatoma, and much clot, followed by pus, came away The swelling vanished, the tumour was small and gave no trouble

I removed a fibroid uterus a year or two ago in a case where ascites was marked In this instance there were about eight pints of free fluid in the abdomen, yet no history of any kind of injury The tumour was a bulky, œdematous fibroid which had grown rapidly within six months of the operation and weighed 4 pounds 6 ounces. The omentum adhered strongly and its vessels were much dilated, whilst there was old standing disease of the appendages. Recovery was rapid There was no reason to suppose that the mere presence of the fibroid caused ascites in this case. Nor was it set up as the result of injury, but there was pelvic serous inflammation which extended higher The ascites and the marked œdema of the tumour were probably two results of some common cause not easy to explain. There was inflammation of the appendages a condition which does not tend to cause serous effusion The relation of pelvic inflammation to fibroid tumours is another question which will presently be considered

Howard Kelly goes so far as to state that ascites is a complication by no means rare in fibroid disease, if we take into consideration lesser as well as larger quantities of fluid.[16] He relates a case where he found nearly 12 pints in the abdomen, no history of any injury is given Kelly states that "the cervix was jammed down on the pelvic floor by hard uterine tumours filling the pelvis." Perhaps œdema played a share in causing ascites The cause of ascites, says Kelly, is not known and I think that we must agree with him. There was evidence of lymphatic obstruction in my own case, but this in itself can hardly cause ascites. In fibroid disease where free fluid is conspicuous for its rarity, marked obstruction of the lymphatics of the broad ligament is perhaps plainer to the eye than in the case of any other tumour, whilst in ovarian growths free from œdema and from dilatation of lymphatics in the adjoining broad ligament ascites is not rare. Mechanical irritation cannot explain the rarity of the complication in question. Cannon-ball like ovarian tumours (the exogenous cysts of pathologists) are often associated with ascites, but cannon ball uterine fibroids (groups of subserous myomata) are often found in a perfectly dry peritoneal cavity Let us remember that ovarian dermoids, which certainly cause mechanical and yet worse forms of irritation, are rarely complicated by ascites, whilst free fluid is proportionately common in true fibroma of the ovaries even where its surface is smooth[17] Free papilloma is always associated with ascites.[18]

Infection cannot explain the rarity of ascites in fibroids, for septic changes in these tumours are not unknown, yet it is not recorded that they are complicated by ascites, whilst there was no evidence of infection of the tumour in any of the cases of ascites which I have just related. Septic changes are frequent in ovarian dermoids, yet, as in these uterine growths, it is rare to find them associated with dropsy In short, the rarity of ascites in fibroid disease of the uterus remains unexplained and its cause in exceptional cases is obscure. I admit that true ascites and pure passive hydroperitoneum have not been carefully distinguished in clinical records, though ascites as a symptom in visceral disease was manifestly absent in the cases which I have brought forward The subject deserves more attention from general pathologists and physicians.

ABSORPTION OF FIBROIDS.

In 1893 when preparing a monograph on this subject[19] I was able to discover about 50 relatively recent reports of which under 40 were worth consideration. Since that date we have heard little about "absorption" of fibroids until last summer when Professor Murdoch Cameron once more turned our attention to this subject[20] "I can remember," said he, "quite a number of cases which were sent to me as fibroid tumours of the uterus, but which with rest and potassium iodide eventually disappeared. *These cases very closely resembled fibroid growths*" This observation was the starting point of correspondence between Professor Cameron and myself[21] He replied to my inquiries about the clinical symptoms of these cases, saying that "on examination an extensive hard swelling was found in each case behind the uterus and extending backwards to the sacrum. Its outline could not be defined." Professor Cameron suspects them to be inflammatory or traumatic in origin,[22] but adds that as there was no operation he could not give their pathological characters He felt sure that they were not cases of impacted fibroid growths of the uterus and so he treated them with drugs and rest. The hard masses slowly disappeared Though sure that the swellings were not "impacted" fibroids, Professor Cameron implies by the use of that term that they were fixed. No doubt some of the alleged cases of absorption of fibroids were really instances of disappearance of parametric exudation fixing the uterus, still, in others the uterus was reported as moveable. For my own part, I was never a great believer in reported cases of rapid "absorption" of fibroids. Putting aside shrinkage after necrosis there seems to be no such thing as a 'quiet" and molecular disintegration of a fibroid, the molecules being carried away by the blood vessels and lymphatics and not discharged into the vagina.

Kleinwachter, Kidd, and John Phillips each report a case of disappearance of a fibroid after delivery I collected these three cases and reported them in my monograph Professor Cameron believes that it is the capsule, or rather the surrounding normal uterine tissue, that undergoes involution during the puerperium He further declared that he "has never observed the absorption of the original growth which simply returned to about its original size" Many of us will agree with Professor Cameron who at least indicates a source of fallacy Yet the three observers just mentioned are men of authority

There remains another source of fallacy in respect to the absorption of fibroids after delivery Might not the fibroid have been expelled in some instances during parturition and have been overlooked? Boissard[23] recently reported a case where the placenta came away spontaneously after a normal labour It was preserved and examined by a midwives' class as a matter of routine A fibroid polypus as big as a hen's egg was discovered about three inches from the edge, with its fundus firmly adherent to the chorion and its pedicle torn through Thus a tumour as big as a hen's egg may be delivered unobserved with the placenta. Let us remember that a submucous fibroid might be discharged in that manner, mistaken for part of the after birth by a careless nurse, and then thrown away A gynæcologist might have detected the tumour during or before the pregnancy Supposing that he did not attend the labour yet had the opportunity of examining the patient after convalescence he would be liable to come to a false conclusion about the vanished fibroid. The disappearance of a correctly diagnosed fibroid may be the result of necrotic changes and in association with that complication I shall presently refer to a case related recently by Stouffs of Brussels where a necrotic fibroid was removed three months after delivery Lastly, I believe, as I did in 1893, that destructive *inflammatory* processes account for the disappearance of fibroids in most cases where there was no pregnancy and that this was clearly the explanation in my own case [24] Mr Skene Keith and Dr. Gerald Garry[25] are active supporters of electricity in the treatment of fibroids. Mr Keith declares that he has seen more than 20 fibroids disappear after Apostoli's treatment. But Dr Garry admits that out of 70 cases of uterine fibroids under his treatment he can report "but two in which the shrinkage almost amounted to disappearance." In one of the two the disappearance followed "a violent inflammation which lasted over three weeks," not due, according to Dr Garry, to the treatment but to gross carelessness on the part of the patient.

Whilst rapid absorption is so doubtful there can be no doubt that many fibroids gradually vanish. The process which brings about this result is probably necrosis, or more strictly speaking, the aseptic necrobiosis not rare in fibroid tumours. The source of nutrition fails and the tumour softens and becomes infiltrated with fluid which disintegrates its fibres.[26] When extreme shrinking results the condition may be taken for absorption. The same change no doubt causes the disappearance of fibroids at the menopause, as is usual though not constant. Professor Cameron sees no reason why fibroids should not by some at present unknown means be made to disappear Perhaps in some of the cases cured by drugs the tumour was really a fibro-myoma and necrosis was induced by the action of the drug. The same may be said of treatment by electricity It is now advisable for us to consider this question of necrosis independent of diminution of the fibroid.

NECROTIC FIBROIDS

Necrosis of a uterine fibroid is a change of great clinical interest. It is usually accompanied by distinct impairment of health, whilst the advent of anæmia in a case where menorrhagia is absent is, I find very characteristic Dull pain is felt in the pelvic region and the tumour is often tender to the touch The temperature is usually, but not always above normal and the pulse is quick and weak. On examination the tumour is found enlarged and softer than before the symptoms just described set in. Obscure fluctuation is often to be detected, no sloughing structure presents at the os externum, and the fornices are free. There is tenderness in the pelvic and hypogastric regions. Pathologically this change consists in a quiet death of the tissues without the agency of germs, infiltration of red fluid full of septic organisms sometimes observed is no doubt secondary The tumour becomes infiltrated with fluid which softens and even breaks down its fibres, this infiltration is sometimes erroneously named 'œdema, it is ultimately followed by shrinkage of the mass. Thus, as I have remarked, many cases of rapid "absorption were instances of shrinking necrotic tumours The dead fibroid remains in its place, at least, for our present purpose I may be allowed to insist on that clinical limitation. For sloughing and expulsion into the vagina are not quite what we understand by necrosis. The same may be said of discharge of the growth through the abdominal walls after the development of abscess, as described by Olshausen, but I suspect that in some such cases there is first an injury [27] then a suppurating hæmatoma develops, as in a case of my own, to which I referred when speaking of ascites after injury to a fibroid. An adjacent fibroid growth might easily loosen until it lay in the abscess. Olshausen considers that it is the capsule, not the tumour, that sloughs in such cases. In necrosis of a fibroid as a rule the capsule remains healthy, but the tumour sometimes discharges its substance into the vagina, as in Schmauch's case.[28] Perhaps it is advisable for us to find out what kills fibroids Abuse of ergot has been given as a cause, and I think on reasonable grounds in some cases. In more than one instance under my observation electricity had been tried for the cure of the tumour, but I admit that it is difficult to determine cause and effect Necrosis it would appear, usually occurs when the patient's general health is impaired or when the tumour is badly placed for nutrition. General ill health may unfavourably influence a fibroid hitherto innocuous, whilst a bleeding tumour, by impairing the general health, may insure its own destruction. Pregnancy without doubt may cause necrosis of a fibroid. Stouffs of Brussels[29] has recently reported a case where a subserous myoma was found to be necrotic when removed three months after delivery [30] The patient complained that the tumour was tender, as was also observed in at least two instances of necrotic fibroid in my own practice, which I shall presently relate This tenderness is of importance, it is remarkable how rare it is to find a uterus tender to touch, so unlike the appendages which bear handling badly even when only a little inflamed. Adhesions of intestine, rare in fibroid disease, could not very well cause necrosis, but in one case under my observation they were beginning to set up true septic changes in a fibroid already necrotic

I have operated on several cases of necrotic fibroids, some of which deserve consideration In two general malnutrition seemed to be the direct cause of the complication.

The first patient was a sickly neurotic single woman, aged 45 years. When 19 years of age she suffered severe shock in a railway accident and was laid up for 20 years. She never regained perfect power over the bladder For two years the patient had menstruated freely, clots and membranes had been expelled about eight times during that space of time, but there were no exhausting hæmorrhages. The uterus rose to a few inches above the pubes and came down into the pelvis, it was tender to touch, especially below The temperature was about 99° F at night I operated in November, 1901, sparing both ovaries. The tumour was a necrotic submucous fibroid in the posterior wall of the uterus, it weighed only 14 ounces but was very bulky A year after the operation the patient was in good health, the period was represented by a little dark "show" every fortnight.

The second patient was a neurotic spinster, aged 29 years, subject to phthisis which had abated under suitable treatment a year previously when a fibroid was diagnosed. The tumour rose to about four inches above the pelvis. It became tender with rise of temperature. Then attacks of retention of urine set it. The period grew a little more copious than before for a reason detected after the operation. I operated in February, 1899, sparing the left ovary The uterus contained a characteristic fibroid as big as a cocoanut yet weighing only one pound one ounce, it was very soft and contained much semi fluid yellowish material. A hard fibroid as big as a cob-nut projected under the mucous membrane immediately above the os internum and was doubtless the cause of the menorrhagia. The patient's general health was greatly improved a year later

General malnutrition seemed to account for the necrosis of the tumour in these cases. The cause may in other instances be local, the tumour being placed so as to interfere with its own nutrition. I will relate a case of the kind when I come to speak of the "cup-and ball" fibroid which fits closely into the pelvic cavity The commonest cause of necrosis seems to be a combination and reaction of general and local influences—above all, hæmorrhage with its consequence, anæmia.

In 1897 I operated on a woman, aged 42 years, who had suffered for two years from severe menorrhagia and inter menstrual hæmorrhages and was extremely anæmic. There was rise of temperature at night, which may mean clot retained in the uterine cavities, inflammation of the appendages, or, as in this case, necrosis. Both ovaries were removed as they showed signs of cystic degeneration There was a big necrotic fibroid in the posterior wall of the uterus The patient rapidly regained her health.

[28] Loc. cit. Note that in Schmauch's case there was anæmia without hæmorrhage and that the fragments of the necrotic fibroid were not septic they recalled the aseptic intra uterine maceration of a retained fœtus.

[29] Fibrome Utérin en voie de dégénérescence nécrobiotique post partum, Bulletin de la Societé Belge de Gynécologie et d'Obstétrique, vol. xiii. 1902-03 p. 71.

[30] Some cases of alleged "absorption" of a fibroid after delivery may be explained this way The necrotic tumour becomes softer and ceases to enlarge.

In several cases of multiple fibroids which I have removed where the patient was much reduced by menorrhagia some of the growths were necrotic.

Adhesion of intestine could not very well cause necrosis but might set up septic changes in a fibroid already necrotic This was the case in a remarkable instance which I spoke about in association with the relations of the round ligament to fibroids The growth in this case was so placed that its vascular supply was inadequate for its support and thus necrosis occurred Adhesion of intestine caused more prejudicial changes In no case could I trace necrosis of the fibroid to inflammatory disease of the ovaries and tubes That complication did not exist in any of the cases above mentioned, whilst in none of the instances of inflammatory disease of the appendages presently to be related was there any necrosis of the fibroid. As long as the necrotic fibroid is removed so that the knife passes below it and none of its substance touches the peritoneum there is no special danger in operating upon it, nor are its semi fluid contents always septic, so that if spilt during removal bad results do not always follow But sometimes it is otherwise, and in the days when I used the serre-nœud I lost a case where some turbid fluid escaped into the peritoneal cavity during hysterectomy Necrosis seemed due to general ill health in this instance The fluid was certainly septic In any case where general infection of the uterus is evident (as in removal of a fibroid uterus in the puerperium) panhysterectomy is indicated In conclusion, it is clear that small necrotic fibroids cause more constitutional disturbance than a trifling amount of menorrhagia can account for Such cases often justify hysterectomy when the fibroid is small, as it is a source of general ill health The surgeon however must not urge the removal of a small fibroid on the plea that it may become necrotic.

CUP AND-BALL FIBROID

The term "cup-and ball myoma" has been applied by Howard Kelly[31] to a globular fibroid tumour which fits more or less firmly into the pelvis It is mainly of interest on account of the difficulty experienced by the operator in drawing it up, whilst the securing of the broad ligaments and uterine arteries is never easy when the fibroid is spherical and developed chiefly in the lower part of the uterus The necessary manœuvring cannot be satisfactorily described in a lecture nor can it be performed by any fixed rule, as Kelly implies The most accessible broad ligament must be tied and divided, then by traction towards the opposite side aided by more or less rotation the uterine artery is reached and ligatured at this stage, in many cases the tumour is free enough to be drawn up, so that the opposite broad ligament and after it the corresponding uterine artery may be secured, the cervix being divided last. Sometimes a corkscrew must be used to draw up the tumour In most cases, however, Kelly's method of cutting through the cervix after the first uterine artery has been ligatured and divided, securing the other uterine artery, dividing it and ending this stage of the operation by tying and cutting through the remaining broad ligament, is easier than the more usual plan of working through both broad ligaments to the cervix The latter is the better plan where there is a bulky vascular tumour in the fundus with a narrow cervix and wide broad ligaments easily reached below the morbid growth.

The cup-and ball fibroid is, as the above remarks show, chiefly known for the difficulties which it offers to its removal. The most important question as it directly concerns the patient s interest, is, Why should it be removed at all? The truth is that many fibroids of the body of the uterus pass through this cup-and ball stage before they are detected by the patient or by the medical attendant. If the tumour be light and if it does not invade and therefore shorten the broad ligaments so as to impair its own mobility it will cause no inconvenience. Ultimately, when the patient is lying on one side or stooping, it will roll upwards above the pelvic brim and settle for good in the abdominal cavity These cases are often seen in out-patient departments and in private, they largely make up the series of fibroids which can be pushed up with a clinical history of subsequent comfort or which can be kept up more or less by a pessary Whether they grow larger *after their ascension* or give trouble through menorrhagia is not to the point. Not rarely, on the other hand, does the cup-and ball fibroid give rise to special troubles in its vicinity, and it is one of the forms of uterine myoma that tends to arrest its own development by changes prejudicial to the patient's general health. A good example of necrotic changes in a cup-and ball fibroid occurred this year in my own practice

The patient was a single woman 41 years of age She was thin and anæmic, but hardly through loss of blood, as, though the "show" at period had increased during the past six months, it was *not more* profuse than is often seen in association with perfect health, and no bleeding ever occurred between the periods Dr F J McCann detected a tumour when she consulted him for fever and mucous vomiting which had continued for three weeks, there was also sharp pain in the hypogastrium and left iliac fossa sometimes set up by micturition The upper part of the mass lay half way between the pubes and the umbilicus. The cervix lay completely to the left of the lower part of the tumour which seemed to occupy the right fornix I operated on March 13th There were no adhesions and no evidence of inflammation external to the tumour, which was quite spherical. Its lower hemisphere fitted firmly into the pelvic cavity, whence it was extracted with difficulty I succeeded in reaching the broad ligaments and saved the ovaries, the right was plump and bore a large corpus luteum, the left was flattened out by pressure and atrophied. After turning down an anterior peritoneal flap I managed to ligature the uterine vessels which lay in an awkward position between the prominent under surface of the tumour and the short cervix. The rest of the operation was easy The tumour which I now exhibit (weight two pounds, two ounces) consists of the *greater part of the body* of the uterus with a spherical necrotic fibroid in its posterior wall. The degeneration was probably due to the position of the tumour, which prejudiced its nutrition, its lower part pressing against the broad ligament, the squeezing of the left ovary against the pelvic brim in part accounted for the pain, whilst the necrotic changes impaired the patient's health She declared that she had felt very ill for some months before the tumour was removed, whilst seven months after the operation her general health was excellent. The majority of cases of small spherical fibroids lying in the pelvis neither get impacted nor necrotic, therefore the subject need not further detain us.

FIBROID UTERUS AND DISEASE OF APPENDAGES.

Oöphoritis, salpingitis, hydrosalpinx, pyosalpinx, as well as simple perimetric adhesions, may exist in association with uterine fibro-myoma. Inflammation of the tubes and ovaries cannot cause a fibroid to develop or if it can be shown to do so in some cases it is no essential cause. We often see appendages, perfectly healthy and innocent of any "pinx" or 'itis," associated with every type of fibroid. On the other hand, inflammation of the appendages, puerperal, gonorrhœal, &c., may occur in a patient subject *to this* common form of uterine disease Dr C J Cullingworth[32] believes that the complication is always a coincidence. In 100 cases in his own practice salpingitis was not once met with, an experience which seems exceptional. He fails to see how a fibroid, except *in the* comparatively rare instance of its having become septic, can be directly responsible for a condition like salpingitis which so far as we know at present is always the result of infection We must all of us agree with the latter part of Dr Cullingworth's argument—the statement that salpingitis is due to infection Necrotic fibroids are often not septic, but on the other hand they not rarely contain germs Still, in none of the cases of necrotic fibroids of which I have been speaking was there salpingitis, whilst in none of the cases of salpingitis (of which more will be said presently) was there necrosis of the fibroids.

Necrotic fibroids, then, as we learn from experience, do not necessarily infect appendages, whether they themselves be originally septic or free from germs. But Dr Cullingworth implies that only a septic uterus can infect the tubes and ovaries previously healthy I think that in some cases where there is disease of the appendages they have been infected, not by a septic uterus, but by septic germs pent up in the uterus We often find in the uterine cavity an accumulation of sanious fluid and broken down endometrium which cannot freely escape owing to obstruction near the os internum, but though these products of disease cannot get out germs may get in, perhaps introduced by the sound, as in a large class of cases which Matthews Duncan grouped under the common heading "chronic gynæcology" It is easy to understand how the tube might thus become infected by the contents of the uterine cavity This probably occurred in a case of bilateral pyosalpinx which will presently be described In some cases of pyosalpinx (which is often a primary disease as far as the tube is concerned) it is possible that a hydrosalpinx first developed and that its contents afterwards became purulent owing to infection from adherent intestine This cannot always be the explanation—as, for instance, in three cases in my own operative practice where there was pyosalpinx without any adhesions. These cases and others induce me to believe that infection is often derived from the contents of the uterine cavity I repeat that the tubes and ovaries remain quite healthy in a majority of cases, and so far my experience is more like that of Dr Cullingworth than that of Twambly (Boston) and Lawson Tait who imply that this complication exists in 50 per cent of all cases of fibroid.[31]

[32] An Analysis of 100 Cases of Uterine Fibro-Myoma, Journal of Obstetrics and Gynæcology of the British Empire, vol. i p. 28 last paragraph

I need not dwell on numerous cases in my own experience where the ovaries were imbedded in soft perimetric adhesions and the tubes congested, if not inflamed. This condition does not demand their sacrifice. In six cases of uterine fibroid I encountered disease of the appendages sufficiently severe to increase appreciably the difficulties and dangers of an operation. Fortunately, no ill results followed in any case. In one the inflammatory disease was bilateral and severe, the fibroid was small, so that the appendages were removed and the uterus was left behind. In five hysterectomy was performed, and it is important to note that in three out of the five the inflammatory disease was unilateral and I was able to save one ovary

The first patient was 47 years of age, subject for several years to menorrhagia and some hypogastric pain. There was a history of perimetritis after delivery when the patient was 22 years of age, since then she had never been pregnant and suffered from no pelvic symptoms. Dr W B Addison of Thornton Heath detected fibroid enlargement of the uterus. I discovered a tender tense, irregular mass behind an enlarged uterus and operated in November, 1897 I found bilateral hydrosalpinx with ovaries the seat of old inflammation There were multiple adhesions of omentum to the bladder, uterus, and appendages. The fibroid growth was distinct but hardly rose above the pelvic brim. I removed the diseased tubes and ovaries without any trouble In May 1902, four and half years after the operation, Dr Addison informed me that the patient was in perfect health and had never menstruated since her recovery The fibroid seems to have remained stationary

In one patient where I removed a bleeding fibroid over four pounds in weight there was a large pyosalpinx on the right side. I ligatured the right ovarian vessels and took away the dilated tube unemptied and attached with the ovary to the uterus. This is the right manœuvre whenever practicable. The left appendages perfectly healthy, were saved. There was no feverish reaction during convalescence and the patient was quite well two years later

In a *second* case I also discovered a pyosalpinx on one side (the left) and saved the opposite appendages, but owing to the shape of the uterine tumour I saw that it would be safer to take away the pyosalpinx separately, which I did without spilling any pus Two years later the patient was in very good health.

The third case where I saved the appendages on one side was curious, the patient was a very anæmic woman, aged 41 years. She was delivered of her only child 24 years before the operation, necrosis of the tarsal bones of the right foot occurred during the puerperium and the foot was amputated. For six years she had been troubled with severe hæmorrhages and occasional attacks of pain and tenderness. When I examined her there were much pain and all the symptoms of pelvic peritonitis There was pyosalpinx on the left side. I found that it was safer and easier to remove the diseased tube and ovary first and then the uterus was amputated, the right appendages being saved. Three years later the patient was in good health.

In the three cases just related there was pyosalpinx but there were no adhesions The source of infection could hardly have been on the peritoneal side, as when an adherent hydrosalpinx suppurates I suspect that in the third the infection might have arisen from decomposing material in the uterine cavity

In two cases the disease was bilateral and both appendages had to be removed with the fibroid uterus

The first patient was 38 years of age, she aborted about the *fourth* month four years before operation. For five months she had been laid up with severe abdominal pains when I operated and removed a bulky fibroid 4 pounds 12 ounces in weight. The tubes were diseased and the right ovary showed signs of early cystic degeneration The cause of the inflammatory disease of the appendages was not clear There were no adhesions, as in the three previous cases Infection might well have arisen from the uterine cavity

The second case has already been noted when I spoke of ascites associated with fibroid. The patient was 43 years of age and single, and I could not find out any cause for the chronic diseases of the appendages which, on the other hand, may have played a share in producing the ascites. In this case there were free omental adhesions to the right appendages and to the tumour The patient remains in good health nearly two years after the operation.

The operator should never leave a suspicious tube behind, its cut surface is a source of germs and favours adhesions The aspirator is advisable to empty an adherent pyosalpinx which cannot be detached and drawn up without fear of rupture. But when the dilated tube is free it is best to wrap it in sterilised gauze after separating it from the ligatured ovarian vessels and either to take it away unopened with the uterus or else to tie it in two places close to the uterine cornu and to cut between the ligatures and remove it separately with the ovary Forceps should not be used for this purpose, as they will be contaminated by the pus, whilst as both uterus and tube have to come away the ligatures will do no harm. I think that I have said enough to show that inflammatory disease of the appendages is of sufficient frequency in cases of uterine fibroid to be taken into account both as regards the medical and surgical treatment of that complaint.

Having spoken of inflammatory disease of the ovaries a word or two on tumours in relation to uterine fibroids will not be out of place. A considerable number of cases of ovarian cyst coexistent with fibro-myoma of the uterus have been recorded.[34] But in the great majority of cases each of those forms of tumour exists by itself and it would be frivolous, in the face of clinical and pathological evidence, to attempt to make out that uterine fibroids are caused by ovarian cysts or that the cysts are the cause of the fibroids. Fibroma of the ovary is not a very rare disease and is independent of uterine fibroid, it is significant that in the few recorded cases of pure myoma of the ovary, including one where I was the operator and where the ovary was cystic, there was no new growth in the uterus, contrary to what might be expected. Malignant ovarian tumours also have no associations, save coincidence, with uterine fibroids. Lastly, no uniform change has been discovered in ovaries associated with uterine fibroids which could imply that it played any part in causing the development of the fibro-myoma Several foreign authorities as well as Mr A Corrie Keep and myself have examined numerous ovaries associated with uterine fibroids. We have all come to the conclusion that any marked change seemed to be due to the pressure of the uterine tumour which may reduce the ovary to a flat ribbon, or to obstruction to the circulation in the ovary, which sometimes causes blood cysts to develop I have found hæmatoliths[35] in ovaries associated with uterine fibroids and fibroid disease of the uterus existed in the case recorded by Hector Mackenzie,[36] the discoverer of ovarian hæmatoliths. Blood cysts it may here be observed, have been detected by

---

[31] See Stanmore Bishop Uterine Fibro-myomata," p. 49 Twambly was speaking specially of interstitial fibroids.

[34] Mrs. Scharlieb (An Analysis of 100 Cases of Fibro-myomata Uteri Journal of Obstetrics and Gynæcology of the British Empire October 1902, p 330) detected cysts of one or both ovaries in 23 per cent. of these cases The cysts must however have been in most of these cases dropsical follicles or as the authoress herself states "changes due to interference with the pelvic circulation and with the nutrition of the ovaries by the fibroids." Experience shows that out of all cases of fibroid far less than a quarter have coincident cystic tumour properly so called

[35] Blood Concretions in the Ovary Transactions of the Obstetrical Society vol. xl 1893 p 214 The specimen is in the Museum of the Royal College of Surgeons of England, Pathological Series 4482, C

[36] Blood Concretions in the Ovaries Transactions of the Pathological Society of London vol. xl., 1889 p 215

Olshausen and Littauer[37] in ovaries left behind after removal of the uterus, they seem to be a result of disturbance of circulation due to tying the uterine branch of the ovarian artery close to the cornu. They concern not the pathogenesis of fibroids but rather the treatment of the ovaries in hysterectomy which we have already considered The changes seen in the ovaries in some instances may play a part in aggravating hæmorrhage or otherwise, but this question remains obscure.

LARGE VESSELS IN FIBROIDS THE SOUFFLE.

The vessels in a large fibroid of old standing are often extremely dilated. Therefore a souffle may be heard on auscultation, which, of course, must not be confounded with the pulsations of the abdominal aorta audible through any solid tumour In two quite recent cases the souffle was loud, transmitting in one a thrill to the palm of the hand placed on the surface of the tumour In the other the sound as heard through the stethoscope simulated the souffle of pregnancy perfectly The patient was a married woman, aged 30 years, but she had not been pregnant for ten years She was extremely anæmic and much reduced in health from profuse floodings The cervix was small and firm and for other reasons pregnancy was improbable, but I could well understand when I auscultated this case how in slightly different circumstances pregnancy might reasonably have been diagnosed Thus the cervix might have been soft and a spherical outgrowth in the lower part of the tumour might have simulated a fœtal head The tumour weighed over four pounds and the veins were enormous One ovary was left, but the case is too recent for drawing any conclusions about the effects of the preservation of ovarian tissue. There have been no troublesome after effects up to the present

I have dwelt on the souffle, but not solely as a curiosity It means that there are big vessels and their existence implies increased risk of the hysterectomy A big vein should be carefully tied on its proximal side Clamping, invaluable as a temporary resource in the course of the operation, inflicts much damage on the tissues immediately surrounding the vein. Hence it is better to avoid clamping a big engorged vein on its proximal side, or if that be actually necessary the vein should be ligatured below the clamp and the tissue bruised by the instrument carefully trimmed away The ligature should never be stout No 2 silk will answer well for a vein Careless clamping, needless handling of structures on the proximal side of the line of incision, and stout ligatures not only increase the chance of inflammatory exudation, parametric abscess, and intestinal adhesion, but when vessels are large these practices naturally promote thrombosis and embolism.

An Address

ON

CERTAIN PRINCIPLES AND METHODS IN THE SURGERY OF THE PARALYSES OF CHILDREN

Delivered before the Huddersfield Medical Society on Nov 6th, 1902,

BY ROBERT JONES, F R C S EDIN,
HONORARY SURGEON ROYAL SOUTHERN HOSPITAL, LIVERPOOL
HONORARY SURGEON LIVERPOOL COUNTRY HOSPITAL FOR CHRONIC DISEASES OF CHILDREN

MR. PRESIDENT AND GENTLEMEN,—The subject upon which I venture to address you is one which has interested me for many years and is well worthy of careful study In these days, strange to say, when so much is written on every branch of medicine the surgery of the paralyses of children has received but scant attention and that only in odd places and at odd times. There are many reasons suggestive of the explanation. To the general surgeon the subject presents many difficulties It abounds in detail and demands a patience that only enthusiasm can supply Operations, if they are performed, only attain their purpose when followed by prolonged, intelligent, and carefully thought-out after treatment, and this involves not only a practical knowledge of the sequence of events but a very real faith in certain fundamental principles Short of this faith the surgeon is half hearted in his measures and the patient and friends lose that confidence which inspires hope. The surgeon therefore, should know the theory of his subject and be able definitely to direct practically the mechanical details which are the accompaniment of all operative aid What would we think of a physician who, having made a diagnosis, leaves his unfortunate patient in the hands of a chemist who is asked to administer what he thinks to be an appropriate drug? And yet this is not a travesty but the grim experience of hundreds of paralytic cripples in this country They pay their consultation fees and are then despatched to the instrument maker who is merely desired in the most general terms to fit on a suitable "appliance" Is it any wonder, therefore, that quackery abounds and that the unfortunate patient is, so long as money lasts, relegated to suits of armour bristling with screws and ratchets? The treatment of paralytic deformities is both mechanical and operative. The one is inseparable from the other and the surgeon who is not a mechanic is little better than the old orthopædic surgeon who, without any operative education, looked upon a complicated splint as the universal panacea To the late Mr H O Thomas belongs the credit of having preached the gospel of simplicity as applied to splints In paralytic affections his only implement was a tenotome and yet so skilful was he in mechanical resource that he rarely failed to rectify the most obstinate deformity From him I learned the value of rest in restoring power to over strained muscular fibre and the immense importance of postural prophylaxis in relation to deformity Since his death many important advances have been made on the operative side but the mechanical principles he enunciated are in advance of much of the teaching of the present day

ACUTE INFANTILE PARALYSIS

I will deal first with certain aspects of acute infantile paralysis viewed chiefly from its clinical side We all recognise the great importance of this subject, if only from the fact that next to rachitis it is the most prolific source of deformity, a deformity which never disappears spontaneously Whenever we meet with a paralytic deformity with shortened muscle or diminished joint movement it can be safely assumed that, either from lack of knowledge or from neglect, a condition has arisen which could quite well have been avoided Joint malposition due to muscle shortening or contracture arises from insufficiently opposed muscular action or from faulty posture due generally to the influence of gravity Either condition the surgeon's art should easily enable him to prevent Provided we know in any given case the etiology of its deformity we must not be content to meet it half way but should endeavour to prevent it from ever making its appearance. In a completely paralysed arm the deformity to prevent is one of extension of the wrist and elbow and partial flexion of the fingers At the ankle it is extension and inversion or eversion, at the knee flexion, at the hip flexion, often with external rotation. The causation of these deformities has been often discussed, but of one thing we may rest assured and that is that the action of antagonistic groups is neither the sole cause nor even the most important etiological factor This is evident when we note that deformities occur when paralysis of all the muscular groups is complete, and, furthermore, that when paralysis is incomplete the shortened or contractured muscles are sometimes found to be the paralysed ones We must, indeed look upon several factors as instrumental in the production of paralytic deformities, such as gravity, body weight, the shape of articular facets, and, to a lesser degree, unbalanced muscular action To take an example if all the muscles governing the foot are paralysed and walking is not attempted the deformity will be precisely that which any foot assumes when left unconsciously hanging during anæsthesia—that is an equino varus, the fixation and muscle-shortening being quite secondary If, however, walking has been the habit there will be an equino valgus or calcaneus in response to superincumbent body weight applied in the one case to the inner side of the foot or in the other to the back of the heel. Similarly if crutches have been used and the knee has been allowed to swing flexion is the result, which is the position naturally assumed by a limb whether paralysed or not which is left a mere pendant to the pelvis If, however, the limb be used for walking other deformities may occur—hyper-extension or genu recurvatum if the body weight falls on the heel and genu valgum when the body weight is brought to bear upon an everted foot. And so every deformity is produced in a manner which can be easily ascertained when we examine the patient and his habits, and I emphasise the matter because of its prophylactic bearings. In the limb not completely paralysed contractions of the more powerful groups of muscles act very harmfully on their opponents, and it is the recognition of this fact which constitutes the keynote to both the mechanical and operative treatment.

---

[37] Note on a Specimen of an Ovarian Growth removed after Vaginal Panhysterectomy Centralblatt für Gynäkologie No 39 1902, p 1025.

In the past we have all been too much governed by the pathology of the affection to do justice to its clinical aspect Because certain groups of muscles have barely responded to stimuli and have remained inactive it is too often assumed that this is due to cell destruction in the motor area. This assumption, if correct, would render useless any effort on the part of surgery What we have to recollect, however is that the cell destruction is not so extensive as would appear and that the affection, so far as the majority of the cells are concerned, is a transient and a recoverable one. We have no time to consider the many interesting points in connexion with pathology, more especially its infective origin, but we must not be led astray by any reports made on the cords of children dead months and years after the onset of the affection. At this stage many secondary changes have occurred and we have yet much to learn concerning the changes and degenerations of cells secondary to muscular desuetude. Careful and extensive investigation of the cords of subjects months and years after the loss of limbs, and similar experiments on growing animals, would throw an interesting sidelight upon the cell changes found in poliomyelitis of long standing Let me take as an example paralytic wrist-drop This deformity is of slow growth and when untreated is never recovered from. The principles governing its treatment are so little understood that at the present moment there are thousands with crippled useless hands who have received neither hope nor help from whomsoever they have consulted And yet the majority of such deformities are most amenable to treatment and do not even require the knowledge which the practice of a speciality involves Let me for a moment allude to cases in order to add clinical weight to my remarks.

CASE 1.—Some 15 years ago a youth, 19 years of age, came to me with loss of power in his arm and a typical wrist-drop. He gave the history of what he called a "tooth" stroke when he was two years old. He had no power of voluntarily extending his hand and the wrist could only be extended by the surgeon when he exercised considerable force , as the wrist became extended the fingers flexed He had but slight movement of the fingers, just enough to enable him to hold a stick while the wrist was acutely flexed. For reasons which I will explain later I was able to tell him that even at this period, 17 years after the onset of the affection, his hand could be made quite useful. In less than two years he was able to flex and to extend his wrist and to perform movements of considerable nicety with his fingers.

CASE 2.—A young woman 23 years of age, who had been the subject of poliomyelitis 20 years previously, presented herself with a contracted hand which could only be extended by moderate force. When forcible extension was adopted the wrist could only be extended by permitting flexion of the fingers. Advice had been sought from several neurologists and massage and the battery had been unanimously recommended For some years all treatment had been discarded and the only attention paid to the hand by the patient was in endeavouring to keep it out of sight. After carefully examining the muscles I assured her that treatment would ultimately prove very satisfactory Again in less than 18 months she was enabled slowly but with considerable precision to flex and to extend her wrist and to move her fingers separately

It is needless to multiply cases but to many of us such results would seem incredible until the explanation in all its simplicity were vouchsafed. These two cases had remained untreated because muscles powerless from desuetude were mistaken for muscles paralysed from cell destruction. To begin with perhaps the whole arm was paralysed , then the strong group of flexors recovered , later the extensors. The flexors, however, having first got well, overpowered the extensors and, aided by gravity, became shortened or contractured while the extensors were stretched out and lengthened. This, then, is the secret of the prolonged disability—a group of muscles placed at mechanical disadvantage had become impotent from desuetude. Well, then, how is the surgeon to know the case where he can assuredly, as I did, give a confident prognosis? The test is simple. He asks the patient to move his fingers in the direction of extension The patient says he cannot The surgeon then grasps his wrist and still further forcibly flexes it. The patient is then asked to extend his fingers from their new position. If he succeed ever so little a favourable prognosis may be given. Should he fail then treatment is of no avail. The treatment is based upon Thomas's theory of muscle shortening and consists in a recognition of the mechanical principles governing the production of contractures. In the paralytic wrist one group of muscles is lengthened and another is shortened by posture and treatment must be directed to the reversal of these conditions. In other words, we must slowly stretch and lengthen the flexors and place the extensors in such a position that their structural shortening will ensue. There is no opportunity at present to enter fully into methods, but when I state that the wrist and fingers must be placed in hyper extension for very many months the principles of treatment will be sufficiently appreciated The test of recovery consists in the power of the patient voluntarily to extend his fingers from the splint upon which his hand rests. I have dwelt at some length on this aspect of the question because the principle underlying it has received but scant allegiance and furthermore because it influences our every effort whatever joint or limb be affected We must not attempt to treat a weakened set of muscles without first rescuing them from being overstretched and we must carefully note that we can but restore to action elongated muscles by maintaining them in a slackened posture There are many analogies in confirmation to which I could draw your attention, but I will confine myself to the consideration of only one or two We all know that congenital club-foot is not a paralytic affection , we are also conscious that apparently after treatment has resulted in rectification a so-called recurrence is frequently chronicled. Why should that be? I am quite sure that I can give you the explanation. It is due entirely to the fact that the extensor muscles have not sufficiently recovered to resist the action of gravity—in other words, the patient is unable to hold the foot at right angles. A recurrence therefore, merely means the formation of a paralytic deformity exactly as it occurs in poliomyelitis where the extensors of the toe are affected. It can be prevented by keeping the foot over corrected until the extensor muscles have, as the nautical expression goes, "taken in their slack." When a talipedic foot can be voluntarily raised to above a right angle a recurrence cannot possibly occur Here, then, is an admirable confirmation in a non paralytic case of impotence from desuetude. You will note, therefore, that we have clinical data which will enable us to say whether or not a paralytic drop wrist is recoverable, and we know that the severity of the contractions and the duration of the disease do not contra indicate a favourable prognosis. As an aid to prognosis we may note that the structural shortening of the flexors is a more serious impediment to recovery than the long duration of the disability

In illustration of the value of preventing a pull upon paralysed muscle, you may be interested in an experiment which I made some months ago A relative in whom I was much interested was attacked by paralysis of the facial nerve, probably due to effusion into its sheath. For several weeks only a slight improvement was manifest. I therefore fixed on his face an apparatus so designed as to draw the angle of his mouth on the paralysed side well up towards the ear In less than a fortnight he had so far recovered as to be able to dispense with it, feeling very grateful for its manifest help A similar instrument tried upon a second case when the paralysis had lasted four months with but little abatement, acted almost as a charm and was worn for a month—only because the patient feared a recurrence from too prematurely discarding it.

An interesting confirmation of this principle occurred in two cases of paralysis of the shoulder girdle when all the muscles above those governing the hand were affected. The arm lay helplessly by the side and even the hand responded but imperfectly to the will. The elbow was flail like and quite uncontrolled by any group of muscles. Such an arm is obviously of but little use to a patient, having to be lifted by the opposite arm It struck me that it would be advisable if possible permanently to fix the arm at an angle so calculated that the hand might be brought into contact with the face and neck Arthrodesis of the elbow I knew to be an unsatisfactory operation and I decided, therefore, to make the fixation by means of skin incisions The arm was first brought to an angle of 45 degrees, and I judged by the relative position of the arm to the forearm how large a piece of skin it was necessary to remove. The elbow was next extended and a diamond shaped incision was mapped out and the skin removed The upper angle of the wound was next attached to the lower and the bare surface of the lower triangle lay in juxtaposition to that of the upper triangle. A scar was thus formed sufficiently firm to hold the elbow flexed In two out of seven cases which I operated upon interesting phenomena followed. Paralysis was thought to be complete in the biceps and brachialis anticus, but some months after the arm was flexed flexion power was restored to the elbow This power was brought about by the postural release from strain cast upon the muscles and still further elucidates the question we are discussing

I trust that I have been able to impress upon you the importance of not confusing muscles which for years have been useless with muscles which are positively paralysed It is this confusion which has hindered both physician and surgeon from accurately gauging in these cases the potentialities of recovery Treatment must be obviously conducted with a view of preventing, or of correcting, structural shortening of muscular groups This in the hand generally means hyper extension of the wrist, in the elbow flexion, and in the knee extension and a rectangular fixation of the ankle

TENDON TRANSPLANTATION

Considerable assistance has been afforded to paralytic children by the recent introduction of tendon transplantation and the revival of arthrodesis Tendon grafting consists in attaching a healthy tendon either to a paralysed one or to the periosteum and, so to speak, changing the sphere of its action. It is quite a mystery how an amicable arrangement between mind and muscle is brought about, for a muscle hitherto directed to evert the foot is now asked to invert it and by the intervention of some law of adaptation it obeys. What interesting possibilities in connexion with the nervous system this suggests. Already I have operated upon over 50 cases and without entering into any details it may be interesting to chronicle my experiences.

The operation in my hands has been most successful where one muscles or one group of muscles has been paralysed. This is exemplified in paralysis of the peronei or of the tibiales In one case reinforcement comes from the extensor proprius pollicis and tendo Achillis, in the other from part of the tibialis anticus and again the tendo Achillis Transplanting the peroneus longus into the tibialis posticus or the converse is sometimes disappointing because of adhesions by the way and the angular direction which the healthy muscle is forced to take The operation should not be performed with the object of strengthening partially paralysed muscles or muscles weakened by elongation. In such cases our opportunity comes for testing the value of what I have stated regarding the mechanism of shortened muscles If any operation be called for, lengthening of the shortened tendons and shortening of the lengthened ones are clearly indicated. Again, in flail like joints tendon splicing is of no avail, because superincumbent body weight is too fatal an antagonist. Another most important point is to employ the nearest available tendon, if it be sufficiently strong rather than one from a distance, and, where it is possible, the selection should be made of a reinforcing muscle the line of which is parallel to the reinforced Take, for instance, a talipes calcaneus where we would by preference strengthen it by the aid of the peronei, or in paralytic valgus where we can with advantage command the services of the extensor proprius pollicis. In analysing my failures I ascribe perhaps the principal share to a want of success in preventing the reinforcing tendon from taking a tortuous route Another cause of failure may be avoided if the operator makes a point of completely correcting—or, better, even over correcting—a deformity before transplantation is performed. For instance, a girl walks with paralytic valgus and has done so for years The foot cannot be placed in inversion without the application of great force. If transplantation of a slip of the Achilles tendon is to be effective the foot must first of all be kept inverted by mechanism until all strain on the inner aspect of the foot has been removed. I would further urge that if tendon is to be spliced by tendon let it be done as near its insertion as practicable so as to avoid as much as possible a yielding of the paralysed section which we know is apt to occur Whenever the tendon can be transplanted into periosteum I am convinced it should be done, care being taken to secure a really firm hold of the tissue When attached to tendon a neat splice should be done, many failures are due to clumsy bulky excrescences which encourage adhesions and otherwise obstruct the easy gliding of the tendon. Finally, the proximal part of the reinforcing tendon should be fixed into the paralysed tendon, so that it be maintained as tense as possible, otherwise we have to face the problem of a slack tendon which cannot do its work.

If these practical points be remembered by surgeons and a watchful eye kept upon the first attempts at walking in order that body weight be correctly exercised on the tarsus, tendon transplantation cannot fail of a good and lasting reputation

ARTHRODESIS

There is another class of case which has interested me greatly—I allude to those paralytic patients with joints either hopelessly flail like or sufficiently so as to demand unceasing mechanical attention The difficulty and expense connected with the purely mechanical treatment of these cases, extending as it does over the whole of a lifetime, are an effective barrier to the poor of our cities The recognition of this fact induced me to urge at the meeting of the British Medical Association of 1894 a revival and extension of operative procedures which for years had remained in abeyance. I allude to the operation of arthrodesis which aims at transforming a flail limb into a member as rigid as the splint which it is desired to discard In a large majority of the so-called paralyses of the lower limb the psoas and iliacus muscles are unaffected and all mechanical means are therefore based, if they are to be of real use, upon the integrity of the muscles The knee and ankle are kept fixed and the psoas muscle is destined to carry the leg splint and all In consequence these weakly paralytic patients easily tire of the weight of their supports and therefore lose the opportunity which presents to strengthen their only pair of muscles of progression.

The operation consists in opening the joint with a sharp gouge peeling the cartilage off the whole articulation in the case of the ankle, and gouging the bone in the case of the knee, keeping the joint completely at rest for some weeks subsequently and for a long period fitting the limb with a simple apparatus which will enable the patient to walk without throwing a strain upon the newly fixed joints An excision is more than the case requires and involves a greater sacrifice of tissue than an already shortened limb can spare. To expose the knee I make an incision across the front of the joint, covering fully half its circumference, and curved so as to pass below the lower end of the patella. The flap is turned up and all the vessels are ligatured I next remove the semilunar cartilages and with a sharp short-bladed knife or gouge peel away the cartilages and the underlying layer of bone, so as to leave a raw surface over the whole of their extent. The crucial ligaments I generally leave intact. The structures are then carefully reunited by deep and superficial sutures, no drainage-tube of course is employed, and the wound is well covered with sterilised absorbent wadding

The operation may be carried out in the ankle joint in one of two ways, according to the circumstances of the case In old cases where the foot is deformed and assumes the equino-varus variety the astragalus is well to the front. In such I force the foot into a position of extreme equino-varus and make an incision in front of the external malleolus following the line of the ankle joint and dividing all structures down to the astragalus, generally only severing the peroneus tertius tendon The other tendons are held aside and the articulating surface of the astragalus is exposed With a gouge or knife several grooved portions of the articulating cartilage are removed If complete bony ankylosis of the ankle be desired it will be necessary to gouge bone. If a fibrous ankylosis be wished it will be sufficient to peel off parts of the cartilage. The ankle is kept extended while some pieces of the articulating surfaces of the tibia and fibula are removed. A few vessels are tied, the foot is placed in its normal relation to the leg, and a suture or two close the wound A pad of wood wool tissue is applied over all and this being firmly bandaged the procedure is complete. In other cases the astragalus is more easily approached from behind and in such the foot is firmly flexed on the leg and an incision down to the bone is made along the external border of the tendo Achillis. The posterior ligament is now freely divided and the gouging takes place as in the former operation. No serious mishap has occurred in any of my series of over 100 cases. Every wound but three has healed by first intention , and, contrary to expectation, those cases where trophic changes were most marked healed as readily as those whose nutritive conditions were nearer normal

In talipes calcaneus where the paralysis is not complete, a deformity often accompanied by pes cavus and for which Willett's operation of shortening the tendo Achillis is performed, I recommend a modified arthrodesis It gives distinctly satisfactory results. Willett's operation is rarely successful, for the moment we try to put a weakened tendo Achillis shortened by operation against body weight exercised during locomotion it can only have one result and that is a fresh and speedy yielding of the tendon. If, however Willett's operation, *plus* exsection of cartilage, be performed we shall obtain considerably better results, for on opening the joint from behind we can shorten the tendo Achillis and remove sufficient cartilage to limit the action of the ankle to about 20 degrees The same procedure may with benefit be applied where in addition to an elongated heel tendon the tibiales have been completely paralysed, producing a deformity of calcaneo-valgus with difficulty rectified manually

I may mention in connexion with arthrodesis of the ankle that one sometimes fails in young children to secure sufficient fixation, and for some months I have removed the upper half of the astragalus and the inner malleolus of the tibia so that the tibia may fall with greater stability on a good square surface The result is very satisfactory and in a completely flail like ankle is, I think, more suitable than the recent operation described by Whitman of New York of complete removal of the astragalus, an operation I have performed on four occasions

Before leaving the subject of poliomyelitis I would desire to draw attention to another class of paralytic patients who are the subject of fixed deformities. The hips are flexed and so are the knees, while the ankle is generally extended If the little patient be made to lie down marked lordosis of the spine occurs. There has never been any attempt at walking, save perhaps a swinging, crutch supported gait. Power may be found in one sartorius and in one psoas muscle. Can such a case be made to walk and, if so how? If we determine to try we will first divide each tendo Achillis and place the ankles in rectangular splints We will next exsect a V shaped wedge from each flexed knee, the wedge being sufficiency large to allow of the easy extension of the limbs. For a few weeks the limbs are retained in this position and a splint similar to a double Thomas's hip is prepared. The correction of the hip deformities must next be commenced This must be prosecuted very vigorously Of all flexion deformities paralytic flexion of the hip is most intractable and generally the shortened structures are on the outer side of the thighs. A bold incision must be made and the fascia and every constricting band divided freely until several degrees of flexion are overcome The patient is then kept upon his double Thomas's splint and for weeks if necessary until the lordosis disappears. This is not assisted by recourse to femoral osteotomy, an operation of very little use in paralytic hip. As soon as the back is straight we place a pair of calliper splints on the little patient and crutch aided let him learn to walk. I know of no sensation more delightful to myself as a surgeon than that I experience when I see one of these crawling little cripples standing erect before me.

Time will not allow me to delay longer over spinal paralysis and I have therefore given you but a brief practical *résumé* of surgical methods as they appeal to me, endeavouring to enunciate principles in regard to the behaviour of muscles which must always influence, and sometimes govern, us in the line of treatment we adopt

ON CEREBRAL PARALYSIS OF THE SPASTIC TYPE

From spinal to cerebral paralysis is not a long step and yet what a different field it is to explore. The patient in a spinal case is generally bright and happy entering into the spirit of our treatment often with intelligent appreciation while in a cerebral case he is uninviting irritable, and almost always dull perhaps the most neglected object within the radius of our art. In the short period still at our disposal I desire to point out certain lines of treatment which offer us great encouragement to persevere in our efforts on the behalf of such patients. This year I have already written on the spastic type of palsy and I must beg your kind indulgence while I repeat the conclusions forced upon me in the consideration of a large number cases. Although it is quite impossible to discuss fully so complex a subject as cerebral paralysis I should like to indicate certain types of the affection where surgery may with advantage be employed. For descriptive purposes cases may be grouped under three headings (1) infantile hemiplegia, (2) cerebral diplegia, and (3) spastic paraplegia. My own experience would lead me to the conclusion that cerebral diplegia is the commonest group, but of 859 cases which I have collected from various sources 510 were hemiplegic, 30 were monoplegic, 142 were paraplegic, and 157 were diplegic The diplegic and paraplegic groups are congenital affections whilst infantile hemiplegia is usually acquired Infantile hemiplegia generally appears before the fourth year and is most commonly preceded by convulsions and by acute febrile symptoms, markedly in contrast to the advent of adult hemiplegia The deformities are of very rapid growth The arm and leg are powerless and the reflexes are exaggerated The foot is arched and adducted, the knee is bent, the hip is rotated inwards, and the femur is flexed. The arm clings to the body, the elbow is flexed to a right angle, the wrist is dropped, the hand being pronated and deviating to the ulnar side, while the fingers tightly grasp an adducted thumb Rigidity comes on nearly always and is increased on passive movement or when the child attempts to move. The aphasia is motor and accompanies either right or left hemiplegia. Inequality of growth is the rule, but while the leg hardly ever shortens more than an inch it is not uncommon to note three inches of difference in the arms. From the point of view of treatment the following facts may prove useful if remembered (1) The arm is more permanently and severely affected than the leg, (2) movements are performed spasmodically, slowly, and without precision, and (3) the power of dorsiflexion of the hand with simultaneous extension of the fingers is lost and usually the hand has no adduction power In the lower limb general rigidity is accompanied by extension of the foot, contraction of the knee, and flexion and adduction of the hip

The cerebral diplegic group is far and away the most serious condition to treat We have here, of course, to deal with both arms and feet. Unless the hands can be used the surgeon is deprived of his chief allies in the treatment of the limbs. Where the spasm is confined to the limbs alone we give the name of "spastic paraplegia," or 'Little's disease" The vast majority even of these cases present mental deficiencies of varying extent and in a considerable minority athetotic movements are also noted.

A severe case of spastic paraplegia brought to the surgeon at the age, say, of 12 months is characteristic. Usually contractions have occurred at the hip or knee, the child's legs are rigid the toes point down, there is usually no internal rotation, and adduction is not sufficiently severe to cause a crossing of the limbs. The reflexes are exaggerated, the patellar reflex not usually causing a knee jerk but a leg-jerk. If the little patient is held by his arms there is no endeavour to separate the limbs, and should the toes be brought to the ground and an effort made by the child to walk both limbs move synchronously and in parallel lines When passive separation of the limbs is made, although it is easily effected, one can see and feel the antagonistic efforts of the powerful adductors If at a later stage the patient is able to walk several changes will be noted. The adduction will be more marked, the scissors walk will have developed, and a characteristic dragging of one knee round the other will be noted, which becomes more pronounced when any attempt at running is made. The body pressure is mainly transmitted to the ball of the toe. These contractures, however, at this stage are generally spasmodic and there is no appreciable shortening in muscle length This shortening occurs at a still later stage and is known as contracture. In quite a number of cases the patients are in a hopeless position as far as walking is concerned. Any effort they make to move only serves to throw the muscles into violent contractions and the legs into extreme adduction The most severe type of contractions in the legs may be associated with but very slight mental defects and unaccompanied by diplegia.

Before discussing treatment I will briefly touch upon the pathology of spasmodic paralysis, if only to suggest how futile are operative procedures directed to the primary lesion. The pathological conditions in hemiplegia, paraplegia, and diplegia are the same in kind. The symptoms are due to the retardation of growth resulting generally from embolism or thrombosis, together with changes in the spinal cord. In later cases one finds wasting and sclerosis of the motor tracts with often a loss of substance in the form of cavities or cysts known as porencephalus. These cysts occur on the surface of the brain and sometimes dip fairly deep into it. They seem to be a late result in a growing brain and to have produced an extensive scar substitute for cerebral tissue Should the porencephalus or sclerosis be unilateral hemiplegia results. If the scar is bilateral diplegia or spastic paralysis results. The lesions therefore are a late product of a hæmorrhage an embolism or localised encephalitis. In the cord degenerations of the pyramidal tract or of the lateral columns are to be found

The treatment of spastic paralysis has been too solely in the hands of the physician for much real progress to have been made. Indeed, from medicine in this affection we have but little to expect apart from very indirect results, and we have only to scan the text-books on neurology to realise the note of pessimism which is sounded. I would argue that a large proportion of children suffering from severe spastic paralysis may be transformed into useful members of the community, improved both in body and mind by surgical efforts, enabled to walk with comparatively little deformity, and generally only requiring the aid to be derived from one or two sticks

We must place in a group outside remedial art the idiot, the microcephalic, and that violent irritable type of diplegic, so often seen, subject to fits and active athetotic moments who has generally lost all control over his secretions The treatment of any condition short of this may be undertaken with varying success subject to conditions which obtain in any surgical case requiring prolonged attention. For instance, active treatment may be required for two years It would therefore be unwise to admit a case into hospital for two months and then to send it to a miserable home where neglect would be sure to follow Such a case, however after hospital treatment, happy in the care of anxious, intelligent parents, no matter how poor would prove a credit to all concerned Another class which gives the greatest anxiety and trouble is that where the affection of the hands is of such a kind as to promise but slight hope of their assistance to the limbs during walking Before despairing, however, I think it is well to give such hands the opportunity of a careful trial, both as a mental discipline and because success sometimes exceeds expectation. I would divide the treatment of all cases of spastic paralysis into operative and post-operative, for although mechanism is involved in nearly every case there is only an insignificant minority which we are called upon to treat without invoking operative aid.

The treatment of the hand and arm in infantile hemiplegia is distinctly less promising than in the diplegic case, but there are clinical signs to which I would draw your attention which help us to predict either success or failure If the paralysis is complete, or in other words, if the little patient is never known to relax his spasm treatment is futile If he only moves the fingers of his affected hand in conjunction with the fingers of the opposite side the results will in all probability be discouraging In all cases where the parents are able to say in the spirit of true observers that the patient is able to do more with the hand now than a little while ago the success of treatment is assured. Similarly, where any degree of voluntary relaxation of spasm exists apart from an associated movement on the opposite side treatment is emphatically indicated.

Noting that the dominant deformities in both hand and elbow are pronation and carpal flexion, treatment should consist in fixing the elbow supine and hyper extending the wrist. The hyper extension of the wrist should be combined with that of the fingers and a special arrangement should be adapted to keep the thumb at right angles to the palm. The spasm in these cases is often so pronounced that the extension of the wrist and fingers must be brought about very gradually If the elbow is affected by contraction of the biceps and brachialis anticus, supination may be combined with extension If this be not the case the flexed position of the elbow will suffice. If, instead of being firmly pronated, the elbow lies semi prone it is not necessary to treat it and all one's energies should be directed to the hands. If the hemiplegic hand spasm is mild this treatment may be discarded in about 12 months, provided that during the whole of this period the extension has been kept up without intermission. The test for relaxation must be the power of voluntary movement, however slow it may be. It will be noted that generally at this stage the patient in endeavouring to extend his wrist will first of all close his fingers and will only open them on completion of extension. The process is reversed when the wrist is flexed. In order to meet this difficulty the splint employed to extend both wrist and fingers is modified so as to extend the wrist alone and to allow freedom to the fingers.

It is difficult to give a reason as to how improvement comes about, but it may be taken as an axiom that prolonged fixation of spastic muscles in a position opposed to their contraction lessens the severity of their spasm. This is true wherever spasm may be found and its influence may be tested even in spasmodic torticollis, intractable as we know that affection to be It would appear as if the group of muscles at last got tired of trying to pull. At this stage or earlier the surgeon may decide whether in a given case success may be predicated, and, if he is in doubt, operation should unhesitatingly be performed Operation will consist of tenotomy or tendon transplantation. An incision is made over the tendon of the flexor carpi ulnaris just above the annular ligament, another is made over the flexor carpi radialis, and both tendons are divided low down and are taken—(1) the flexor ulnaris to be inserted into the extensor ulnaris and (2) the radial flexor into the radial extensor I performed this operation some time ago upon two spastic children, whom I showed to the members of the Society for the Study of Disease in Children, and in both instances voluntary movements were steadily performed, and one a girl, seven years of age, was able to write quite a respectable hand. My friend Mr A H. Tubby, in order to overcome the spasmodic pronation of the forearm, has changed the point of insertion from the front to the back of the radius of the pronator radii teres and has succeeded in transforming the muscle into a supinator

Tenotomy alone has proved somewhat disappointing though one has had an occasional successful case. The operation should be confined to the division of the flexor carpi radialis and ulnaris. It is, in my opinion, better to elongate the other flexors of the hand by a long median incision such as one would employ in lengthening the tendo Achillis. Tendon transplantation, however, is a better operation, less complicated and more reliable The surgeon's art does not end with the operation and hyper-extension of the wrist, leaving the fingers free, should be practised for a further few weeks In order to prevent adhesions after the operation the wrist should be freely but very gently withal moved in about a fortnight's time Whether an operation has been performed or not the final stages of treatment are identical They should consist in getting both guardian and patient to strive every nerve to urge and to practise movements from simple to complex. The nature of the movements to be practised must be left to the ingenuity of the surgeon. The principle which should govern him may however be here indicated. (1) The movements should be practised slowly and without excitement, (2) they should be made interesting to the child, (3) those opposed to the direction of the deformity should predominate, and (4) those presenting the greatest difficulty should be chiefly practised.

Just a word, before we deal with paraplegia, regarding tenotomy of the spastic muscle Empiricism has taught us that for some reason or other tenotomy lessens both in frequency and intensity the spasmodic element in paraplegia. I do not merely mean to say that division of the tendo Achillis controls spasm in the calf muscles, although of course it does, but rather that spasm in which those muscles are not directly concerned is also influenced This is beyond all question and must have been noted by everybody who has had the opportunity of observing, and the fact has now reached the robust stage when physiological explanations are vouchsafed. Whitman urges that by elongation of the tendon the response to the exaggerated motor impulses is lessened and an opportunity for more effective control is afforded. Discussing the question with Mr Tubby he propounded the theory that once the immediate pathological effect of the central nervous lesion had subsided the spinal cord remains in a state of undue reflex excitability A tightly contracted muscle and tendon tend to augment this condition and so induce in themselves further contractions In other words there is a vicious circle of reflex action which can be interrupted by section of the tendon and diminution of the tension of of the affected muscle and tendon. Lorenz attributes the effect to the shortening of the muscular portion of the tenotomised muscles so that their range of action is diminished. Both these theories of course, refer to spasm in which the divided muscle is concerned and do not explain the diminution in spasm experienced elsewhere We must, further remember that the opponents of contracted muscles are always elongated and weak and that the rest afforded them by tenotomies by relieving them of strain helps to restore muscular equilibrium

The practical deduction from these observations is that no opportunity should be lost of performing a tenotomy Even in mild cases where a spastic tendon is to be felt we need have no hesitation in dividing it. If the surgeon has decided that a case of spastic paralysis is suitable for treatment a splint should be prepared so designed as to keep the limbs in pronounced abduction. The area over the hamstrings, the adductors at the groin, and the tendo Achillis should be suitably prepared for operation The adductors should be first attacked An incision an inch or two long should be made to the inside of the adductor longus This muscle should be seized by a forceps and about three-quarters of an inch of it removed. The limb is then abducted and portions of the adductor brevis and gracilis are exsected in similar fashion. The horizontal portion of the adductor magnus and if necessary the pectineus, is divided and also any tissue, muscular or fibrous, obstructive to an absolutely free abduction of the femur Experience has shown me that although the chief offenders are the adductors longus and brevis nevertheless the deeper muscles often require division. To anyone who has practised the operation the futility of attempts to divide the muscles effectively subcutaneously will be apparent Division is followed with but little hæmorrhage and the wounds are closed without drainage Having exsected the pieces of the adductors each tendo Achillis is divided, or, better still, elongated, for we often note that after division of the tendon outright there is a tendency to walk too much on the heel. Rectangular splints are then applied to the foot. The limbs are then well abducted and the surgeon notes whether there is any obstacle to easy extension of the knees. If there should be (it is not often the case) an open incision must be made on each side of the popliteal space and the tense hamstrings are in turn divided. If these incisions are long enough the fascial contraction can be attacked on either side for it is here that opposition is found. I would discourage the use of a transverse incision as when adopted it often seriously hampers the surgeon s efforts to extend fully the knee by reason of the strain cast upon the sutures. Simple division, however, with fasciotomy usually suffices to allow of easy extension and excision of tendons could do no more. In 1885 when I was at the Liverpool Stanley Hospital there used to be an adult diplegic man always at the gates in a perambulator and on two or three occasions I took him in to try to straighten his contracted limbs On one occasion I removed about an inch from each of the hamstrings but he was mentally so deranged that we did not do each other any credit. I mention the fact, however because Lorenz of Vienna has quite recently written on the advantage of exsecting portions of the hamstrings.

We have now presumably got our patient stretched comfortably upon an abduction frame and we must keep him there for three months The wounds heal very rapidly and suppuration has occurred in the adductor cavity on three occasions only despite the position of the wounds and the number of operations performed , for instance, in 1890 I operated on 27 patients and this may be taken as a fair index of my yearly return At the end of three months the splint is taken off during the day and movements are sedulously practised. For some weeks stiffness exists and often the movements are at first painful, but after a time (always shortened by vigorous exercise) the pain disappears and the effort must be made to walk. The splints are of a simple kind designed to keep the knee from bending The boots should be made of felt with substantial soles. The nurse should be instructed to keep both boots and splints upon the patient day and night, and for the first two weeks frequently during the day abduction, adduction flexion, and extension of the hips should be practised This should be done with and without resistance At night-time the feet should be attached to the side of the bed in order to maintain abduction After the first few days of this later stage of treatment the splints should be removed twice a day and the muscles well massaged and both active and passive movements of ankles, toes, knees, and hips encouraged. Any movement executed in a jerky style should be practised until perfected.

The little patient may now try to walk. It will be noted that one of the difficulties of an untreated spastic child when he tries to walk is the narrowing of the pedestal upon which the trunk rests by reason of adducted limbs Operation has now overcome this and with abducted limbs the body is poised upon a pedestal that is widened. During early training the nurse must see that while walking the limbs are not approximate and that from the first swinging aided by crutches must be prevented. Crutches should not be allowed until the patient has been taught to stand unsupported I need not enter into any more detail regarding this most important stage of treatment, but would add that it affords an inexhaustible field for ingenuity and that upon the intelligence and industry of the nurse very much depends.

I cannot now deal with individual cases, but I may say that I have operated upon patients from 12 months to 20 years of age A large number of these were so bad that they had never attempted to place one foot before the other Some were structurally flexed (contractured) at ankle, knee, and hip A most helpless youth, aged 20 years, with one limb across the other, was able in six months to stand erect and to walk with sticks, and 12 months later he was able to move his limbs north, south, east, and west with hardly an appreciable jerk. Success in an ancient case where so much has to be unlearnt, and where the mechanical stage offers so much difficulty, proves the soundness of the principles I have endeavoured to expound. It is logical to infer that if old neglected cases are amenable to surgical education our prognosis should be very hopeful in the young

With regard to the degree of benefit to be derived from treatment, the parents should be given to understand that under favourable conditions of nursing and tuition the child, aided by the hand or sticks, will be able to walk distances in from 12 months to two years and that with perfectly straight limbs and heels on *terra firma* A large proportion of cases will later manage aided by one stick. Even in the least successful cases parents, mostly having despaired, are full of gratitude. The mental condition of the children obviously improves when their physical defects are remedied and they are enabled to mix with their little friends. Complete recovery in spastic paraplegia is, of course, impossible.

It will be gathered from my remarks that the treatment of spastic paralysis should resolve itself into a system. That system involves operative, mechanical and educational stages The treatment cannot be separated into parts. If the surgeon is not satisfied that the case is to be under his control for 12 months he will consult his reputation best by leaving it alone. Operations not followed up by careful and prolonged after-care give rise to disappointment and discredit. Merely dividing tendons and trusting to massage and electricity is futile and dispiriting

In conclusion gentlemen, I would say that infantile paralysis offers an immense field for surgical enterprise and if I have succeeded in even suggesting to you some of the possibilities your time will not have been altogether wasted.

LUNACY AND LAW THE CARE AND TREATMENT OF PERSONS OF UNSOUND MIND IN PRIVATE HOUSES AND NURSING HOMES[1]

BY ERNEST W WHITE, M.B., M R C P LOND,
PRESIDENT ELECT OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND PROFESSOR OF PSYCHOLOGICAL MEDICINE, KING S COLLEGE, LONDON RESIDENT PHYSICIAN AND SUPERINTENDENT CITY OF LONDON ASYLUM, DARTFORD KENT

MY paper to-day is the natural outcome of the address by Sir William Gowers upon Lunacy and the Law,[2] the views of a London hospital physician, particularly in regard to private patients, given at our last general meeting in London. The discussion which followed was hardly worthy of the subject. Most of the earlier speakers, although eminent general physicians, had had little or no experience in the care and treatment of the insane, therefore when the turn came for those practically acquainted with mental diseases to speak the hour was advanced the audience was weary, and an all too-exacting brevity resulted To day the alienist's side of the question can be fairly stated. My wish is to deal with it as briefly and appositely as possible in order that the discussion may be as thorough as we can make it I hope that all who have had practical experience of single care and of the treatment of mental cases in nursing homes will assist us in our search after truth, that the best results may accrue to those who suffer from this the saddest form of human ailments I propose to treat the subject by a series of questions and answers, with illustrative cases here and there

---

[1] A paper read at the general meeting of the Medico-Psychological Association held at the County Asylum, Mickleover near Derby on Feb 12th, 1903.

[2] THE LANCET Nov 22nd 1902, p. 1369

What is certified single care?—It is the care and treatment of a duly certified person of unsound mind in a private house The forms for admission are identical with those for the admission of a private patient to a public or private asylum or registered hospital There is a like order made by a judicial authority The medical attendant takes the place of the medical officer in institutions, and must visit at stated intervals and make the customary reports to the Commissioners and Visitors in Lunacy A registered practitioner with whom a single patient resides cannot act as medical attendant The residence is approved by the Commissioners in Lunacy and the patient is visited periodically by them and the medical and other visitors for the county or borough. Chancery patients are visited by the Lord Chancellor's Visitors in Lunacy Facilities of access are given to friends by statute. Thus abuses are guarded against and there is efficient official supervision.

What are the advantages of certified single care?—They seem to be (1) privacy, (2) domesticity, (3) secret visits of friends, and (4) the avoidance of the stigma of treatment in a lunatic asylum.

1. *Privacy* —The rich and well to-do try their utmost to keep secret the mental breakdown of any member of the family for well known reasons, hence single care at a distance from home is the desideratum.

2. *Domesticity* —The upper classes often dread the contact of their relatives with other insane patients and complain of the lack of the comforts of home life in public and private institutions These objections are now removed by the villa residences attached to public and private asylums and hospitals for the insane

3 *Secret visits of friends* —In single care the relatives, if so disposed, can visit unobserved and much more frequently than they can in an asylum or hospital

4 *Avoidance of stigma of insanity* —The sting of certification is in the magisterial inquiry Young and inexperienced justices often investigate the cases more fully than is necessary They place too little reliance upon the facts contained in the medical certificates. The terrors of certification are thereby increased The form of the medical certificate needs revision. The term "alleged lunatic" should be removed The word "asylum" should be applied only to an institution for "the chronic and incurable insane." "Hospital for mental diseases" should be used for an "institution for acute and curable cases" The terms "lunatic" and "lunacy" should be removed from the statutes, "person of unsound mind" and "insanity" taking their places For years past the terms 'lunatic," 'lunacy,' and "pauper" have been forbidden at the City of London Asylum and the word 'asylum" has only been used for statutory purposes

What are the disadvantages of certified single care?—(1) The absence of skilled medical treatment, (2) unskilled nursing, (3) monotony, (4) insufficient moral control, (5) interference of friends, (6) limited supervision, and (7) want of tact and business capacity on the part of the custodian

1 *The absence of skilled medical treatment* —The general practitioner as a rule, knows but little of the treatment of mental disease. Psychological medicine has only recently become compulsory in the medical curriculum. Moreover, I am sure that you will all agree with me when I state that the knowledge of the proper treatment of mental diseases is not to be acquired in the rounds of general practice or in the consulting room, or even, at present within the wards of a general hospital.

2. *Unskilled nursing* —The nurses (male and female) having charge of single patients have had no special training, as a rule, in the management of mental cases and, although, perhaps, hospital trained, are quite unqualified for the work No nurse is qualified to undertake a mental case in single care unless possessed of the nursing certificate of the Medico-Psychological Association, which is a recognised guarantee of efficiency The responsibility with single patients is the greater because the nurse from want of skilled supervision is so frequently thrown upon her own resources.

3. *Monotony* —We all know of the many associated amusements and means of recreation provided in institutions for the insane. How dull must be the life of the patient in single care in this respect.

4 *Insufficient moral control* —The moral decadence of the upper and upper middle classes when insane is far greater than of the agricultural and industrial populations Sedentary life, luxury, and high living tend to bad habits. Self abuse is far more common amongst private patients than amongst the rate-paid The moral control—I would rather term it "school discipline"—of our institutions is one of the most potent means we possess for successful treatment. The day is apportioned out to meals, employment, recreation, and amusements. The will is made subordinate to others, bad habits are corrected, and in many instances our patient is thereby conducted back to rational health. [Here Dr White gave details of an illustrative case]

5 *Interference of friends* —With single patients the friends either get them removed as far from home as possible, satisfy themselves that they are well housed, well clothed, well fed, and kindly treated, and visit them only when obliged, for sympathy for the insane relative generally quickly dies, or the patient may be visited much too often, the treatment of the medical attendant and management by the nurse being interfered with to the great detriment of the chances of recovery

6 *Limited supervision.*—Certified single patients are taken for profit by needy practitioners, decayed ladies and others The official supervision of these custodians is limited How can we guarantee in all cases humane treatment by nurses, also proper food and environment at all times? We must remember that the best mental trained nurses remain in the asylum service or become attached to the better class nursing institutes of the metropolis Therefore we have not always the most trustworthy people in charge of the patients under consideration On the contrary, it is an absolute fact that in a great number of cases the nurses in charge have not had any mental training whatever, frequently they are hospital trained nurses who are sent out by institutions to whatever case may turn up I have heard also of asylum laundry maids posing as mental nurses on the books of such institutions.

7 *Want of tact and business capacity in the caretaker* —Decayed ladies and retired nurses are not possessed of much business capacity tact, or energy in the duties of the house

What is uncertified single care?—It is the taking charge of a person of unsound mind (not under certificates) in a private house or nursing home. I believe that hundreds of insane patients of the upper and upper middle classes are at the present time under care and treatment without being certified in the various counties of England and Wales not to say the Channel Isles and the near continent. What happens is this A member of a family, probably with neurotic inheritance, develops mental symptoms. The parents dread certification and because of the so-called "stigma of insanity" avoid as long as possible the alienist physician being called in but consent to a "nerve specialist" being consulted To the neurologist the patient is taken, he duly prescribes and advises After a short time the symptoms become more pronounced and home treatment is impossible, the patient must go away Then the assistance of the decayed gentlewoman is sought, that she may undertake the remunerative care of the insane person or a nursing home is selected with which some practitioner in a suburban or rural district is connected The neurologist sees the case from time to time in consultation. He considers himself to be well qualified to treat this form of disease and in the interests of humanity (as Sir William Gowers tells us) is accessory to an evasion of the law Ultimately in many instances, owing to an exacerbation of the symptoms (some attempt at suicide or homicide, &c.), certification becomes imperative and the patient is sent to a recognised institution for mental diseases It is from these cases many of us have to glean our recoveries and a difficult task it is at so late an hour in the day of disease. Let us consider two or three cases to illustrate uncertified single care. [Dr. White here gave a detailed account of some illustrative cases]

What are the advantages of uncertified single care?—(1) The avoidance of the so-called "stigma of insanity", (2) secrecy, (3) the so-called continuity of medical treatment (doubtful if unskilled), (4) freedom from contact with other persons of unsound mind, and (5) domesticity

What are the disadvantages of uncertified single care?—(1) Insufficient general and moral control of the patient (there is no legal power of detention, for the patient is in full possession of civil rights), (2) the patient's property is not safeguarded from unworthy relatives, solicitors, medical men, caretakers, and nurses, (3) frequently there is unskilled medical treatment, or none at all, (4) unskilled nursing as a rule, (5) monotony in some out-of the-world place, (6) interference of friends, (7) want of official supervision, and (8) incapacity of caretaker

The want of official supervision is, perhaps, the most serious of these disadvantages, for I have heard of inhumane and cruel forms of personal restraint which have been used upon these unfortunate patients even since the passing of the Lunacy Acts 1890–91, and is not this what we should expect with no official supervision?

[Here Dr White gave an account of cruel treatment which had come under his notice]

What is the suggested notification of mental cases?—It is that in all cases of mental unsoundness in which certification and compulsory detention seem needless, and in borderline cases, there shall be a system of notification to the Commissioners in Lunacy by anyone receiving payment to the effect that "A. B is a person of unsound mind and is not a proper person to be detained." It has been also suggested that this notification shall be to the local authority It is presumed in the first instance it will be followed by the visit of a Commissioner in Lunacy or some one deputed by the Commissioners, and in the second by a medical officer appointed by the local authority

What would be the advantages of such notification?—They would be the same as those given under the heading uncertified single care (*vide* above)

What would be the disadvantages?—These again would be identical with those given under uncertified single care (*vide* above) with in addition increased official expenditure from the necessary appointment of deputy or district commissioners to inquire into the numerous class of cases which would rapidly crop up In an article on Lunacy Law Reform in THE LANCET of Dec. 27th, 1884, I suggested the appointment of deputy commissioners in the following terms

"District experts as medical officers of insanity, occupying analogous posts with that of coroner or medical officer of health, with fixed salaries, these officers to be elected from their experience in the speciality, and to be allowed to practise as pure physicians. Their duties would be to examine all supposed lunatics in consultation with the medical man in attendance, to sign all necessary certificates, to visit all single patients and patients in private asylums in their districts, to report thereon from time to time to the Commissioners in Lunacy, and so act as district agents for the Commissioners or Deputy Commissioners. They would have power to order the discharge of any single patient, or any patient from any private asylum in the district, should such a course be desirable on account of recovery or otherwise They would also have authority to prevent the removal of any patient by his or her friends when such removal was calculated to be fraught with danger to the patient or others." Many of the suggested reforms in that article were adopted in the Lunacy Acts 1890-91. This one was not, for the obvious reason—expense.

I am afraid that notification, unless under the most efficient official supervision, would encourage a continuance of the evasion of the law, or at least would delay proper remedial treatment in consequence of the patient not being under proper moral control

What cases are suitable for cure and treatment as certified single patients?—(1) Quiet and harmless tractable imbeciles, (2) quiet and harmless chronic dements, (3) certain general paralytics in the last stage and (4) hypersensitive patients convalescing from melancholia.

What cases are unsuitable?—All others.

What cases are suitable for care and treatment uncertified?—(1) Transient cases of mania and melancholia dependent upon drink and abuse of drugs, (2) certain borderland cases where the symptoms are undeveloped, and (3) other cases in which the symptoms are not severe and which have a definite exciting cause not likely to be long operative.

How should they be protected against abuses?—By proper and complete official supervision. I have been for years past, and am still, in favour of the appointment of deputy commissioners for districts as defined above, such appointments to be made from those skilled in the treatment of mental diseases.

What is the suggested temporary care and treatment of the incipient insane?—In 1899 the joint committee of the British Medical and Medico-Psychological Associations, of which I have been a member by your courtesy since its formation, waited upon the Lord Chancellor at the House of Lords. The committee urged the necessity of early legislation for the incipient insane. It told the Lord Chancellor how numberless borderland cases were smuggled away in the country, the Channel Isles, and on the continent, to avoid legal certification, how their chances of recovery were imperilled thereby, and how the possibilities of inhumane care existed. As a consequence he introduced into the Lunacy Bill of 1900 the following clause, adapted from the existing clause in Scottish Lunacy Law —

1 If a medical practitioner certifies that a person is suffering from mental disease but that the disease is not confirmed, and that it is expedient with a view to his recovery that he be placed under the care of a person whose name and address are stated in the certificate, for a period therein stated not exceeding six months, then during that period the provisions of Section 315 of the principal Act shall not apply

2. The certificate must not be signed by the person under whose care the patient is placed

3. Where a medical practitioner signs any such certificate he shall within one clear day after signing it, send a copy of it to the Commissioners and the Commissioners may visit the patient to whom the certificate refers.

I believe that this clause with its three sections will meet all the requirements of the case for the insane of the upper and upper middle classes provided that the deputy commissioners above named be appointed.

As several of the county and borough asylums are at the present time admitting private patients in large numbers would it not be well that the voluntary boarder system appertaining to the registered hospitals and private asylums should be extended to public asylums? There are many patients—incipient and border line melancholic cases—who lack self confidence and who, if they can place themselves under the sheltering wing of an institution giving them medical and general supervision will rapidly regain their mental balance and thus escape certification. Those who have had ample experience of the voluntary boarder consider the legislation regarding him has been productive of much benefit.

Having surveyed the subject in detail we must now consider the various points, not already discussed, to which allusion was made by Sir William Gowers. The contemplation from the train of the wall of Hanwell Asylum, we are told prompted him to lead a crusade against the existing Lunacy Laws. He thought of those the wall excluded and those it included Now the wall of Hanwell (the oldest of our London county asylums) is an anachronism. The asylums of to-day have no walls and while the buildings include those committed to the humane and skilled care of the medical officers for treatment, they do not exclude those who desire to gain knowledge regarding mental diseases. The lovelorn Kentish cavalier when he wrote in his prison in Westminster the lines the first of which Sir William Gowers quotes little thought they would be applied to an asylum for the insane some 250 years later Let us contemplate these lines —

'Stone walls do not a prison make
  Nor iron bars a cage;
Minds innocent and quiet take
  That for an hermitage;
If I have freedom in my love
  And in my soul am free
Angels alone that soar above
  Enjoy such liberty"

We do not acknowledge the walls as part of our treatment to-day, nor are iron bars necessary in institutions for the insane, they appear (as we have seen) to be only required for uncertified patients in single care. Our cavalier although imprisoned, was happy withal in the freedom of his thoughts.

Sir William Gowers tells us that in many cases certification is harmful and unnecessary Many of us differ from him upon this point. We recognise in certification th means of placing the patient under proper control for treatment, and we are satisfied that the chances of recovery are in many instances greatly increased thereby The cases quoted by him as suitable for treatment without being duly certified were peculiarly unfortunate They all had delusions of persecution, and these patients, as we alienists know, may at any time become actively homicidal or suicidal by impulse. They should certainly all have been under certificates, both in the interest of the public and of themselves. Sir William Gowers states that every patient received for payment and uncertified is a free agent, can leave or be removed at any time Such is not my experience with uncertified insane patients in single care. Furthermore, I do not admit that certification is in any way disastrous to the patient or the painful distress to friends it is stated to be.

Sir William Gowers speaks of the "divorce of psychological medicine from general medicine." There is no divorce They have always been separate and distinct and must remain so from the very nature of mental disease and the treatment demanded. The moral side of this treatment is all important, the medicinal only accessory and that in quite a minor degree. The days of chemical restraint and of the exhibition of medicinal *nostrums* for insanity are past and gone. We have too many proofs of the value of our more enlightened system to wish to revert to them. Let the general body of our profession make themselves thoroughly acquainted with *this system*, *they will then recognise the* vital importance of the daily contact of the mental physician with his patient to control the management and moral treatment of the case, the necessities of which are ever varying

We are told that the "master of method" is necessary for the full and proper development of the normal mind of youth, that a scholar who has not had training as a schoolmaster is unequal to perfecting a student's education in classics, mathematics, or the higher sciences, how much more then must the "physician of method," trained by long experience and daily contact with the insane, be essential for the re-education of the abnormal mind, for the replacing of the unhinged mind upon its hinges, for the dispelling of the hypochondriacal delusions of the melancholiac, and for the calling back to mental life again of the quasi demented patient in mental stupor? Speaking after 30 years' experience as a public asylum physician, and 13 as a lecturer on mental diseases, I would state unhesitatingly that to comprehend the vagaries of the mind diseased, to lead that errant mind back to health, and to recognise the means by which this end can be attained, are problems only to be solved by those who have made the insane their intimate and lifelong study

Note appended Feb 7th.—Sir William Gowers has just published in pamphlet form his address of Nov 20th, 1902, with a Note. I observe that the title is altered It now reads, "An Address on the Prevention of Insanity" Would not "on the Evasion of Insanity" be more appropriate? In the note he draws attention approvingly to Sir William S Church's suggestion that notification should be to the local authority, the facts of each case to be subsequently investigated by the medical officer of health or some other official appointed by the local authority What does the medical officer of health know of mental diseases? Is he qualified to decide such a case? and who is the other official suggested? Who but one skilled in the treatment of insanity is qualified to decide whether the conditions under which the patient is placed are such as are likely to promote recovery or whether certification is necessary in his or her own interest? Sir William Gowers is in error when he states that provision is already made for the reception of border line patients as voluntary inmates of public asylums. At present voluntary boarders cannot be taken in county or borough asylums, but only in registered hospitals and private asylums. He tells us, moreover, that it is a sarcasm to suggest that patients on the verge of mental derangement would place themselves in lunatic asylums. Is he not conversant with that large class of cases of incipient melancholia in which the patient lacks self confidence and self reliance, is imbued with a sense of impending trouble, and consequently eagerly seeks admission within the walls of a private asylum as a voluntary boarder and expresses a feeling of relief when under the sheltering wing of the institution? The limitation which Sir William Gowers takes objection to in connexion with the clause for the treatment of incipient insanity "that no person under this section shall receive more than one patient at the same time," is in accordance with the principle of the Lunacy Acts, 1890–1891, that private asylums are to die out by gradual extinction for no new licence can be granted. To receive more than one patient would constitute a private asylum. Sir William Gowers objects also to the sanction of the justice of the peace being necessary and adds that "such a sanction could only be a useless formality" He forgets that it is right that the liberty of the subject should be taken away only by some mode of judicial procedure

NOTES UPON A CASE WHERE SYMPTOMS OF EARLY GENERAL PARALYSIS OF THE INSANE FOLLOWED A HEAD INJURY,

TREPHINING, REMOVAL OF DEPRESSED BONE, DISAPPEARANCE OF THE SYMPTOMS

BY A. MARMADUKE SHEILD, M B CANTAB, F R C S. ENG,
SURGEON TO ST GEORGE'S HOSPITAL

AND

T CLAYE SHAW, M D, F R C P LOND,
LECTURER ON PSYCHOLOGICAL MEDICINE AT ST BARTHOLOMEW'S HOSPITAL.

ON Dec. 16th, 1902, was seen for the second time a patient, aged 30 years, who exhibited a remarkable group of symptoms. About three months previously he had been thrown out of a dogcart and had sustained a scalp wound in the left frontal region, below the frontal eminence He was also somewhat "concussed," but his symptoms were not considered bad enough to confine him to bed except for a short time. The bone was carefully examined and found to be uninjured. All went well for some weeks, but in about a month's time the patient commenced to suffer from pains in the head, loss of memory, and a vague feeling of "not knowing what he was about" His wife and friends noticed an alteration in his manner and temper He exhibited sudden and violent outbursts of passion and was unfit to carry on the ordinary business and duties of life. I was at that time anxious for him to remain in London, but he returned to the country, and under medical advice rested in bed for some weeks and took the iodides. At the same time all alcohol was interdicted. He got much better, but on resuming a more active life all his old symptoms returned with increased violence Getting alarmed his friends again brought him to London. His mental condition being very peculiar Dr T Claye Shaw saw him on Dec. 18th, and the following is a summary of his remarks —

The patient wore a confused and demented facial expression and had a considerable amount of both facial and general tremor He complained of pressure-feeling over the scalp and declared his inability to perform any sustained mental work There was no disease of the fundus oculi but the pupils were slightly non symmetrical the left being the smaller they reacted to light and accommodation. He could not stand firmly when his feet were placed together nor could he walk along a line when told to plant one foot directly in advance of the other The knee-jerks were present but weak. There was some tremor of speech but the tongue was fairly steady and there was no prominent complementary spasm of the muscles *around* the orbit. When asked to read the paper he misplaced and mispronounced words and altered the spacing The handwriting was to be deciphered with difficulty owing to the crowding of the letters and shakiness of the upstrokes

The prominent mental condition was one of dementia, an apathy and slowness of comprehension in answering ordinary questions. There was an unwarranted sense of bien-être but no illusions could be elicited The friends said that he had become subject to impulsive outbursts and was considerably changed in general disposition He suffered from insomnia and spoke of loss of sexual appetite.

As to diagnosis there was no history of alcoholic excess or of syphilis and the symptoms appeared to be directly traceable to the injury to the head. It was probable that they were due to pressure and the only remedy seemed to be to resort to trephining *as soon as possible* The temperature under the tongue was 100° F

The operation was done on Dec. 19th. On reflecting a semilunar flap including the area of the old injury, and examining the bone critically, a faint crack was distinctly seen. Upwards of three months having elapsed since the injury union had occurred, and without a close inspection the lesion would have been undetected A trephine with the diameter of a shilling was here applied, the bone was very thick and hard On removal of the disc a fracture of the inner table of the skull was evident and two small pieces of bone were depressed deeply upon the dura mater, which was uninjured. No pulsation could be detected. Another portion of bone was removed and then the membranes rose up and pulsated freely There was very troublesome hæmorrhage from a large anterior branch of the meningeal artery This was allowed to bleed, a drainage-tube being introduced beneath the flap Recovery was rapid and uneventful.

Within a day or two of the operation the most marked and gratifying change occurred in the patient's mental condition. He became intelligent and lively and his face assumed a bright expression, quite different from the heavy apathetic, and somewhat morose expression which he had previously shown. He got up in a fortnight, and left for the country in three weeks. He could walk straight, confidently, and well He could sign his name "as well as ever," and despite my remonstrance he conducted some business rationally and well. The knee-jerks were still weak His wife and other relations regarded him as quite restored to his natural mental state. The return of his power of writing was very remarkable, for whereas before the operation he could merely make a series of barely decipherable up and down strokes after it he could write clearly and well. Dr. Shaw again saw him two weeks after the operation when the improvement was very striking The face had regained an intelligent expression, the pupils were equal, and the walking power, as far as it could be tested, was as usual. The improvement in the handwriting was most marked and we possess specimens of his signature made just before and soon after the operation.

Fits of an epileptiform nature, severe pains in the head, and mental disturbances are all found in these curious and interesting cases. In some cases mere thickening of the bone is found and in others a depressed fracture previously quite unsuspected. In others, again, the membranes have been found thickened, and cystic formations, the remains of old blood extravasations, have been detected. The bone should be freely removed, but unless there be a very definite reason it is better not to incise the dura mater in these cases. Should any suspicion of cerebral abscess be present in the mind of the operator the brain beneath should always be explored in the usual manner "The case,' writes Dr Shaw, "shows the good results of early operation before the pressure which undoubtedly existed was able to effect wasting changes The reappearance of pulsation in the brain after the removal of the bone was very striking "

Cavendish place W

A METHOD OF EXAMINING THE PULMONARY APEX

By A. G AULD, M.D Glasg , M R C P Lond ,
PHYSICIAN WESTMINSTER GENERAL DISPENSARY LATE ASSISTANT PHYSICIAN ROYAL INFIRMARY GLASGOW

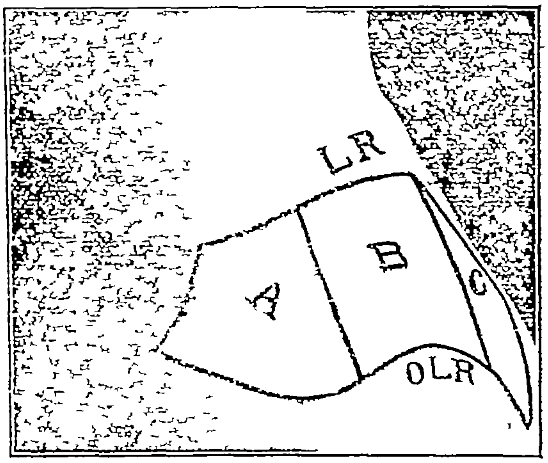
In a former communication[1] I described certain methods of physical diagnosis chiefly applicable to the bases of the lungs and it is now proposed to describe a method of examining the pulmonary apices designed to yield trustworthy indications of the very earliest stage of phthisis. It is commonly recognised that certain general symptoms—e.g , anæmia, indigestion, and evening temperature—may be the only evidences of the commencement of tuberculous deposit in the lung no really trustworthy data being afforded by the conventional methods of examination. The procedure about to be described may materially assist in the detection of such cases

In addition to a large number of clinical examinations I have made a number of observations on the cadaver by sections and otherwise, with a view to determine the relationship of parts and the exact positions of intervening structures. In this part of the work I am much indebted to Braune's Atlas and to some remarkably constructed myographical plates by E. W Tuson of the Middlesex Hospital, published in 1825.

The height to which the apices of the lungs rise varies somewhat. Lying above and between the insertions of the sterno-mastoid, in the curve of the subclavian artery, they reach on an average from one inch to one and a half inches above the clavicles. In some cases they reach two inches. The extreme apex is free and unsupported by bone, but below this the pulmonary tissue is bound down by the rigid first rib Trustworthy observations show that the right apex is a shade higher than the left, but this makes little appreciable difference in practical work. The area now to be considered is situated entirely above the clavicles, extending from these bones to the level of the second dorsal spine, and so includes the entire posterior apical region of the upper lobe.

The method is as follows first, all the resonant area above the clavicles is "percussed out " Percussion is begun at the clavicular attachment of the outer head of the sterno-mastoid and continued upwards, just outside the border of the muscle. Finger to-finger percussion may be employed, but I generally use a vulcanite rod pleximeter, the contact or chest-piece of which is about half an inch in diameter The stroke must be very gentle and its direction vertical, or even rather away from the muscle It will be found that at a certain point above the clavicle the note changes from resonant to dull. This point is marked off with a dermograph. It may be mentioned, that although the apex of the lung lies farther forward than the outer edge of the muscle, percussion over the muscle itself is useless owing to the proximity of the larynx It is essential that the patient hold his head erect without any deviation or rotation to either side Next, percussion is similarly made along the inner border of the trapezius (which is sufficiently evident in most persons) and the point at the side of the neck where resonance ceases is similarly marked off. So, proceeding backwards, percussion is made in an upward direction until the upper limit of resonance is determined all round and the line L R (Fig 1) is brought out. In percussing the parts outside the inner border of the trapezius firm pressure should be made with the finger or pleximeter and the stroke should be fairly forcible owing to the thickness of the tissues (chiefly fat, trapezius, and levator anguli scapulæ). If a pleximeter be used, its contact extremity should be long and narrow

FIG. 1.



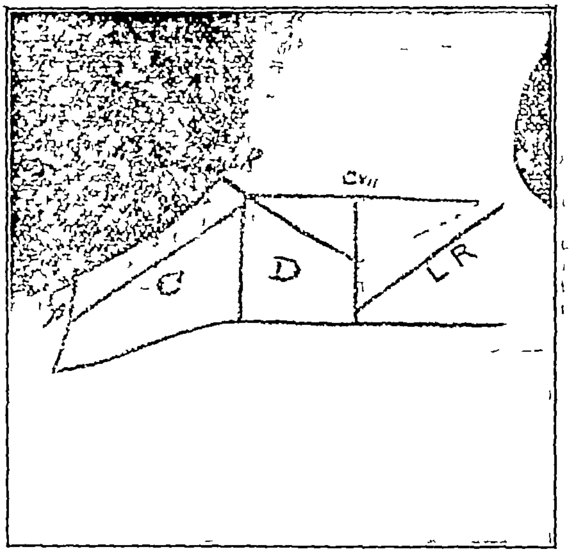
The upper line or limit of resonance being obtained, the outermost or lower limit of resonance is next mapped out. Percussion is begun over the inner third of the clavicle and continued outwards along the bone. About its outer third the note will change. It may be observed that to elicit this change of note mediate percussion (finger to-finger) is better than direct. By successively percussing in the same direction the outer limit of resonance is brought out (O L R in Fig 1) It will now be observed that the upper line of resonance passes obliquely upwards, crosses the interval between the sterno-mastoid and trapezius, still taking an upward direction until its highest point is reached. It then continues almost on the same level for some little distance and takes a course downwards to end at the first dorsal spine The outer line of resonance forms nearly the arc of a circle whose convexity is inwards. In this way the upper and outer limits of the apical area are determined , the anterior limit is the clavicle and the posterior limit is a line drawn outwards from the second dorsal spine to meet the posterior end of the outer line of resonance. Such a line passes beneath the superior angle of the scapula. We have thus the apical region as a somewhat quadrilateral area, mapped out by these different lines.

---

[1] THE LANCET May 31st, 1902, p. 1526

This area falls to be divided into certain segments The first or anterior segment (A, Fig 1) is bounded behind by the inner edge of the trapezius and is thus entirely included in the posterior triangle of the neck. The disposition of the other segments will be best appreciated by a reference to Fig 2 Here it will be observed that a square is formed on the line which joins the seventh cervical and second dorsal spines. It will be found that normally the upper line of resonance runs from the first dorsal spine to the upper and outer angle of the square From this angle a line is drawn parallel to that along the inner border of the trapezius. These lines include the middle segment (B) The posterior segment (C) lies behind and below this, while the vertebral segment (D) is formed by the lower part of the square.

FIG 2.



The key to the detection of incipient disease in one or other apex is familiarity with the physical signs yielded in health. There are certain phenomena which are common to both apices but the signs elicited from the individual segments differ on the two sides Not only is this so, but each segment on either side yields certain modifications in the physical signs which are distinctive of itself, and these are uniform over the entire segment.

In health the upper and lower limits of resonance practically correspond in position on the two sides, provided there be no flaw in the bodily conformation. A slight deviation may be present in the respective positions of the two upper lines owing to the slightly greater height of the right apex Allowance should be made for this in conducting examinations, but it rarely occurs as a disturbing element The distances between the upper and outer lines of resonance should be measured from fixed points on either side and compared This is an important *consideration in* the investigation of disease.

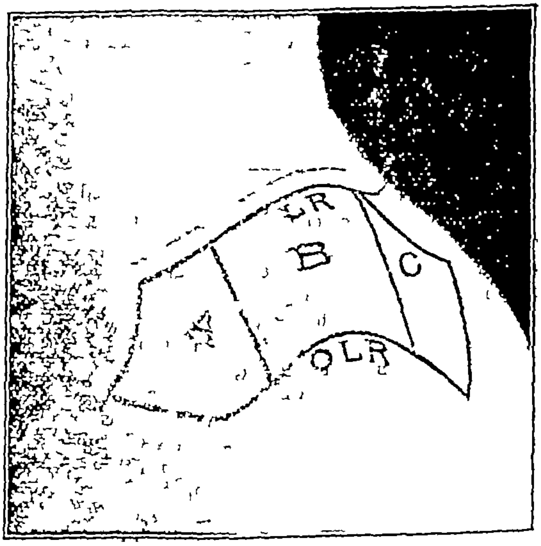
If the pleximeter be placed immediately above the upper line of resonance and percussion be made during quiet breathing or after a forcible expiration, it will generally be found that if a deep inspiration be taken and the breath held, the percussion tone will change from dull to resonant—that is to say there is an *extension* of resonance upwards due to inflation of the apex. A quarter of an inch is about the limit of this excursion, which is represented by the dotted line in Fig 3 Sometimes considerable delicacy of technique is requisite to elicit the phenomenon, and in stout flabby persons it may not be obtainable. In thin muscular subjects with strong lungs it is very evident Its importance lies in this that it be equally produced on both sides Owing to the fixity of the first rib no such extension of resonance is produced at the outer line

In determining the physical signs over the individual segments it is important to note the condition of the patient. Very lean subjects yield signs which might mean disease in stout ones. It is useful to begin by palpating the various segments and comparing the two sides Then the characters of the breath sounds, vocal resonance, and whispering resonance are noted and compared The whispering resonance is of high importance and should never be omitted in any examination.

It is generally *recognised that normally the expiration* sound (which is always "bronchial" in character) is commonly heard over the right apex, at least on deep breathing, and that the vocal resonance is considerably louder than over the left apex This is true both as regards males and females. But such general terms of expression are inadequate and misleading It is necessary to consider each individual case separately from the results obtained in the individual segments.

It cannot be too strongly insisted on that it is only by adopting a standard of comparison that any accuracy can be obtained Such a standard may be defined as follows. Over the anterior segments the auscultatory signs (breath sounds, vocal resonance, and whispering resonance) are most intense, those over the right segment being more *marked than those over the left.* Over the middle and posterior segments on the left side the whispered voice should be inaudible and on deep breathing the expiration should likewise be inaudible, or at least very faint and of short duration. Exceptions to this only occur in the case of very lean or very young individuals, in whom both phenomena may be present It is to be premised, however, that the patient is instructed not to blow his breath out forcibly, but rather to "let it go" On this side also the vocal resonance is more pronounced over the middle than over the posterior segment. On the right side both the whispered voice resonance and the expiration sound—at least in deep breathing—are normally present over the middle and posterior segments, while the vocal resonance is nearly equal over both segments and considerably louder than over the corresponding segments *on the left side.* The vertebral segments have characters peculiar to themselves. Variations are common, which are, however, devoid of any important significance. Commonly they present bronchial breathing, bronchophonous voice, and whispering bronchophony (*not whispering pectoriloquy*) *The sounds are sharp* and "empty" (Skoda) and are due to direct conduction from the larynx through the solid tissues. They are most pronounced on the right side

FIG 3.



Now, if the pulmonary apices be examined in this fractional and comparative manner any deviation from the normal standard, *any evident disproportion* either in *respect* of characters common to both sides or to the *individual segments*, may be justly regarded as a ground for suspicion As early indications of abnormality the *following* points are to *be noted* 1 Failure of the upper line of resonance on one or other side to ascend during a deep inspiration. 2. A lowering of the upper line of resonance in whole or in part as compared with that on the opposite side. Posteriorly for instance, the line may occupy the position shown in Fig 2 (right side), or the fall may be evident only at the anterior extremity, or it may be general all along the line. In estimating this a slight allowance is to be made in favour of the left side but only in that portion of it anterior to the vertebral segment. It should also be ascertained that the line on one side is not abnormally high from emphysema. 3. Indistinct definition of the upper or outer lines of resonance—the resonant and dull areas merging more or less into each other 4 Inward displacement of the outer line of resonance. Should one or more of these signs be present it may be possible to detect some deficiency in the excursion of the diaphragm on the same side.

The results obtained by percussion are next compared with those of palpation and auscultation. The points for consideration are chiefly these 1. The breath sounds disproportionately feeble in one or other of the anterior segments (especially if the right side approximates to the left). 2. Any approximation in intensity in the vocal resonance on the left side to that on the right, either generally or in one or other segment. 3 The presence of whispering resonance and expiratory breath sound over the middle or posterior segment on the left side, noting specially the pitch and duration of expiration, if present on quiet breathing and comparing with the same segment on the opposite side. 4 A discrepancy in the characters of the physical signs over different parts of the same segment, as already mentioned, the signs over each segment should be uniform throughout. 5. Encroachment of the signs pertaining to one segment or another—applying more particularly to the left side, as, for instance, bronchial breathing and bronchophony extending beyond the margin of the vertebral segment

It is most usual when examining the apices in this way to find any abnormality with regard to the lines of resonance existing alongside some change in the normal character of a segment or segments thus immobility of the upper line of resonance may coexist with weak breath sounds in the anterior segment, or a fall in the highest part of the line on the left side with the presence of expiration sound and whispering resonance in the middle segment. On the right side the results of percussion are more especially valuable, as the auscultatory signs by themselves are less definite there. We note that the delimitation of the percussion areas may be verified by (1) the vocal and whispering resonances, and (2) "transsonance. A stethoscope with a small chest-piece (three-quarters of an inch in diameter) should be used[3] It is moved along the segments in such a manner that each successive application partially overlaps the last. At the limits of resonance, the sounds will change. "Transsonance" is a form of auscultatory percussion which is recommended by Abrams. A bone, such as a vertebra or the manubrium sterni, is directly struck with the finger or a hammer while the stethoscope is moved along the parts to be demarcated, the same point being struck all the while. A change of tone occurs in passing to a part of different density By transsonance" we may also compare one apex with another.

It has been pointed out that the auscultatory phenomena over the right apex are less trustworthy, but in addition to the aids just described there is another not to be lost sight of. It is, that in cases of disease the difference in the expiration sound in quiet and deep breathing respectively is much less marked than in health. In disease the bronchial type may be equally well marked in both forms of breathing This is a feature which is of general application.

Occasionally in healthy lungs one hears a few crepitations over the apex (usually in the anterior segment) which are atelectatic in character They only occur in the end of the first deep inspirations taken, and disappear completely after, it may be, one or two inspirations. They differ in character from those due to tubercle, being also more numerous. Tuberculous crepitation, on the other hand, is always persistent

It sometimes happens that a tuberculous apex becomes hyper resonant, either from local emphysema or relaxation of the pulmonary tissue. A difference in the position or in the capability of movement of the line of resonance may then be found on that side, and other differences may be detected in the normal relationships of the auscultatory signs over the segments It is very easy to diagnose a healed tuberculous focus in the apex by this method.

Although little else has been attempted in this communication than to outline the technique employed, its successful application in individual cases is entirely a matter of practice and it may be added, of patience

A RARE FORM OF PURPURA

BY H. LAING GORDON M.D., C.M. EDIN

THE case described below offers, in the present state of knowledge, little more than a pretty subject for academic discussion, but an account of this unusual variety of an uncommon form of disease may supply useful facts or hints to investigators of the nature of purpura.

It does not appear that so far the clinical appearances of the disease or pathological investigation have demonstrated its origin, although they have stimulated ingenuity in grouping and classification. There will be no small difficulty in fitting this case into one particular group The term "purpura," indeed, describes it inadequately, while to call it "Henoch's purpura ' is like putting a fat *cache pot* on a narrow shelf. The bestowal of Henoch s name on a rare group of cases gives them a fictitious importance, the symptoms he described as "added to purpura and articular swellings"—viz, vomiting, intestinal hæmorrhage, and colic —are probably due to internal extravasations of blood, and if this be so "Henoch s purpura" is revealed as a severe form of ordinary purpura. The necropsy on Silbermann's patient referred to in the article "Purpura" in Allbutt s System of Medicine"[1] tends to confirm this view Henoch himself wrote only of "Eine eigenthümliche Form von Purpura," using an adjective which might qualify every case of purpura described since he wrote. The case to be narrated exhibited the symptoms described by Henoch, added to purpura and articular swelling, but had other severe symptoms superadded which did not appear to be attributable to extravasation. An opinion on the origin of a group of symptoms must be, failing definite evidence, a mere individual impression. Dogmatism is a snare but deprecation is craven, and so, in the absence of any specific organism to spare us the use of vague terms, my impression would ticket this case as either "nervous" or ' rheumatic."

The patient, a boy, aged 14 years, known to me as being nervous and abnormally sensitive, persevering at work and plucky in games, was taken ill on Feb 27th, 1901, complaining of pain and stiffness in the limbs and a rash on the legs These symptoms disappeared in the morning but returned the next evening with increased severity, so that on March 1st the head master of the boarding school in which the boy was a pupil asked me to see him. There was no history of previous rheumatism or of any recent illness except slight sickness and transient earache on Feb. 23rd. I found the patient complaining of pain and tenderness in the knees, ankles, elbows and wrists without heat or swelling The temperature was normal and the pulse was 78, a slight fur was present on the tongue. The extensor surfaces of both legs, the inner surface of the thighs and the outer aspect of the elbows were dotted thickly with a purpuric rash, some spots being red, unraised, and recent, others having begun already to fade, while all were indifferent to pressure. The diagnosis of "purpura rheumatica" seemed to be clear but the same evening (March 1st) the onset of colic and hæmorrhage from the bowels proved it to be premature. In 24 hours over a pint of blood was lost, happily this symptom did not recur On the 2nd and 3rd there was no more purpura, but on the 3rd the anterior aspect of each ankle was a mass of urticaria, while the pain was moving from joint to joint. The dorsum of each foot was tender and enormously swollen on the 2nd, but on the 3rd this had disappeared completely giving place to similar conditions of the elbows and wrists. On the 3rd the colic also returned with repeated nausea and vomiting of bile, the abdomen was tender all over The patient s helplessness on the same day was increased by sudden tenderness passes beneath the superior angle of the scapula. We have thus the apical region as a somewhat quadrilateral area, mapped out by these different lines.

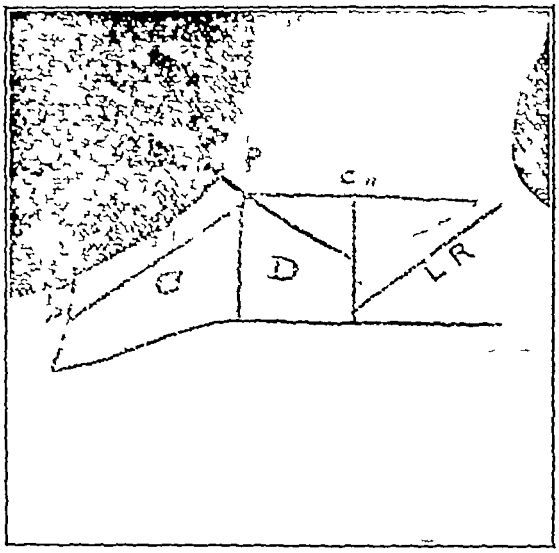
---

[3] Obtainable by unscrewing the ivory chest-piece of the flexible binaural stethoscope.

[1] Allbutt s System of Medicine, vol. v., p. 582.

This area falls to be divided into certain segments The first or anterior segment (A, Fig 1) is bounded behind by the inner edge of the trapezius and is thus entirely included in the posterior triangle of the neck. The disposition of the other segments will be best appreciated by a reference to Fig 2 Here it will be observed that a square is formed on the line which joins the seventh cervical and second dorsal spines. It will be found that normally the upper line of resonance runs from the first dorsal spine to the upper and outer angle of the square From this angle a line is drawn parallel to that along the inner border of the trapezius. These lines include the middle segment (B) The posterior segment (C) lies behind and below this, while the vertebral segment (D) is formed by the lower part of the square.

FIG 2.



The key to the detection of incipient disease in one or other apex is familiarity with the physical signs yielded in health. There are certain phenomena which are common to both apices but the signs elicited from the individual segments differ on the two sides Not only is this so, but each segment on either side yields certain modifications in the physical signs which are distinctive of itself, and these are uniform over the entire segment.

In health the upper and lower limits of resonance practically correspond in position on the two sides, provided there be no flaw in the bodily conformation. A slight deviation may be present in the respective positions of the two upper lines owing to the slightly greater height of the right apex Allowance should be made for this in conducting examinations, but it rarely occurs as a disturbing element The distances between the upper and outer lines of resonance should be measured from fixed points on either side and compared This is an important consideration in the investigation of disease.

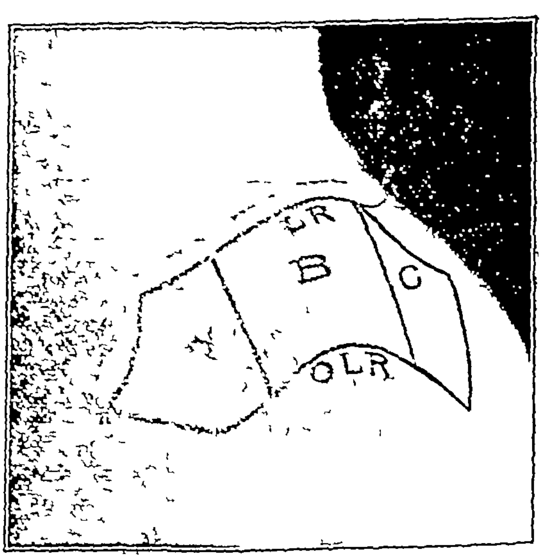
If the pleximeter be placed immediately above the upper line of resonance, and percussion be made during quiet breathing or after a forcible expiration, it will generally be found that if a deep inspiration be taken and the breath held, the percussion tone will change from dull to resonant—that is to say there is an extension of resonance upwards due to inflation of the apex A quarter of an inch is about the limit of this excursion, which is represented by the dotted line in Fig 3 Sometimes considerable delicacy of technique is requisite to elicit the phenomenon, and in stout flabby persons it may not be obtainable. In thin muscular subjects with strong lungs it is very evident Its importance lies in this, that it be equally produced on both sides Owing to the fixity of the first rib no such extension of resonance is produced at the outer line

In determining the physical signs over the individual segments it is important to note the condition of the patient. Very lean subjects yield signs which might mean disease in stout ones. It is useful to begin by palpating the various segments and comparing the two sides. Then the characters of the breath sounds, vocal resonance, and whispering resonance are noted and compared The whispering resonance is of high importance and should never be omitted in any examination.

It is generally recognised that normally the expiration sound (which is always "bronchial" in character) is commonly heard over the right apex, at least on deep breathing, and that the vocal resonance is considerably louder than over the left apex. This is true both as regards males and females But such general terms of expression are inadequate and misleading It is necessary to consider each individual case separately from the results obtained in the individual segments.

It cannot be too strongly insisted on that it is only by adopting a standard of comparison that any accuracy can be obtained Such a standard may be defined as follows. Over the anterior segments the auscultatory signs (breath-sounds, vocal resonance, and whispering resonance) are most intense, those over the right segment being more marked than those over the left. Over the middle and posterior segments on the left side the whispered voice should be inaudible and on deep breathing the expiration should likewise be inaudible, or at least very faint and of short duration. Exceptions to this only occur in the case of very lean or very young individuals, in whom both phenomena may be present It is to be premised, however, that the patient is instructed not to blow his breath out forcibly, but rather to "let it go" On this side also the vocal resonance is more pronounced over the middle than over the posterior segment. On the right side both the whispered voice resonance and the expiration sound—at least in deep breathing—are normally present over the middle and posterior segments, while the vocal resonance is nearly equal over both segments and considerably louder than over the corresponding segments on the left side. The vertebral segments have characters peculiar to themselves. Variations are common, which are, however, devoid of any important significance. Commonly they present bronchial breathing, bronchophonous voice, and whispering bronchophony (not whispering pectoriloquy) The sounds are sharp and "empty" (Skoda) and are due to direct conduction from the larynx through the solid tissues. They are most pronounced on the right side

FIG 3.



Now, if the pulmonary apices be examined in this fractional and comparative manner any deviation from the normal standard, *any evident disproportion* either in respect of characters common to both sides or to the individual segments, may be justly regarded as a ground for suspicion As early indications of abnormality the following points are to be noted 1 Failure of the upper line of resonance on one or right ileo-cæcal region persisted, she therefore took a large dose of castor oil on the afternoon of the 28th with the result that the bowels acted freely but the pains returned with greatly increased severity and there were several attacks of vomiting The girl, of course, was sent to bed again and Dr A Warwick Brown was called in late at night. He at once recognised the case as one of severe appendicitis and arranged for her removal to the Margate Cottage Hospital next day He saw her next morning and finding that the area of tenderness had greatly increased and that the girl was distinctly worse caused her to be taken to the hospital with great care on an ambulance. She was seen by me an hour after admission. There were then well marked signs of general peritonitis, the pulse was over 180, the temperature was 101° F, the abdomen was rigid all over, and no movements were visible with respiration, which were shallow and over 40 to the minute There were occasional ineffectual attempts at vomiting The girl was too bad to elicit where the area of greatest tenderness was to be found, and in view of her collapsed condition we considered the outlook to be distinctly unfavourable.

An operation was decided on and carried out as rapidly as possible, Dr Brown administering chloroform and Dr R. Thomson assisting me. The usual oblique incision over the region of the appendix was made and on opening the peritoneum a quantity of thin pus escaped, this was not offensive and there were no adhesions The cæcum and appendix which was behind it and directed inwards were exposed, and round the base of the cæcum there was some thick white lymph, evidently of some days' standing, and a piece of swollen, inflamed, and œdematous omentum of the size of a visiting card was adherent to the appendix, which was itself swollen, intensely injected, and perforated at its tip It was thus quite clear what had happened the attack had started five days before and the inflamed area was being shut off in the usual manner, but the morbid products had been let into the general peritoneal cavity as the result of the purgative and the consequent violent peristalsis. The appendix and damaged omentum were rapidly removed and an incision two inches long was made in the middle line, through this a large glass irrigator nozzle was passed and a quantity of thin odourless pus welled up from the bottom of Douglas's pouch. A stream of hot saline solution was then directed through the tube and made to flow out through the lateral opening until the solution returned quite clear, when a large rubber drainage-tube was passed through the median incision reaching to the bottom of the pelvis and a similar tube was passed upwards through the lateral incision by the side of the cæcum. Both incisions were then lightly plugged with sterile gauze and left wide open, no sutures being inserted The usual sterile dressings were applied and the patient was got back to bed as rapidly as possible. She stood the operation well, it having taken 40 minutes. On the next morning there was a marked improvement in the condition of the patient, the temperature had fallen to 99° and the pulse to 110 and there had been no more attempts at vomiting There was a fair amount of discharge from each tube and during the night of the operation and the following day the dressings were frequently changed, the gauze plugging was changed at the end of 24 hours. On the 31st, two days after the operation the improvement continued, the temperature was 99° and the pulse was 100 The rigidity had entirely and the tenderness nearly, disappeared, the abdominal walls moved freely with respiration, and the discharge from the tubes having practically ceased they were removed 48 hours from the time of operation. The wounds were after this lightly plugged twice daily until no longer necessary, and from then to the time she left the hospital, four weeks later, with both wounds practically healed, her return to convalescence was uneventful and uninterrupted.

I regret that a bacteriological examination of the pus was not made, but both symptoms and appearances pointed to one of the worst forms of septic peritonitis and I hardly dared to hope for a recovery Possibly it was due to the fact that the intestines, with the exception of the washing out, were disturbed as little as possible. There is no doubt that their removal for cleaning and consequent handling must add greatly to the shock and so places the patient's tissues at a disadvantage in dealing with the organisms that are certain to be left behind in spite of the most careful "toilet." Leaving the wounds open in these acute cases not only facilitates drainage but has another great advantage—the patient is sooner off the table and the period of convalescence if the wounds are carefully dressed, is very slightly prolonged. The other factor in the girl's recovery was the promptitude of my friend Dr Brown in advising surgical interference, as even with all the publicity afforded to the disease in the last few years the aid of active surgery is too often invoked too late.

HÆMORRHAGE IN PREGNANCY A CASE OF CENTRAL PLACENTA PRÆVIA

BY H. T M WHITLING, M.B, B S DURH., M.R.C S. ENG, L R C P LOND

ON Nov 15th, 1902, the nurse in attendance on a married woman sent for me at 7 A.M., stating that labour pains had commenced about three hours previously and that they had been attended before and during her (the nurse's) presence with alarming "flooding" The patient, aged 40 years, was a multipara, with five children, whom I had twice previously attended at confinements (once for twins) and whom I knew to be generally quick in labour and the possessor of a large pelvis and an unrepaired ruptured perineum dating from her first confinement, which gave plenty of vaginal room as it extended rather far back towards the rectum. When I arrived there were numerous signs—such as clots, &c.—on the bed of a severe hæmorrhage and a utensil was nearly half filled with fresh blood which had just been passed while micturating

On examination per vaginam the os was found to be slightly larger than a five-shilling piece and was apparently soft and easily dilatable. Blood was flowing freely and my finger perceived the almost unmistakeable "boggy" soft sensation caused by a presenting placenta. The membranes were intact and bimanually I made out the back of the fœtus to the right and the limbs to the left of the uterus, the vertex was right occipito-anterior Having swept two joints of my examining finger round inside the os uteri and thereby separated the placenta as far as possible, I found that without passing my whole hand into the vagina and through the os I should not be able to reach the edge of the placenta to rupture the membranes, so I determined to tear straight through the placenta itself, seize a leg or foot, and to turn quickly, or, if the head was found low down, as I thought to be the case, to apply forceps and to deliver rapidly, for celerity in the latter procedure I knew that the pelvis and vagina afforded plenty of space and no obstruction and forceps had been used by me before.

Withdrawing my hand I prepared a douche of izal and water at a temperature of 115° F, injected five grains of "ergotin aseptic" hypodermically into the gluteal muscles, and got my forceps ready Pains were now fairly severe and bleeding was free, but the general condition was still not very bad and as my whole attention was necessary for other matters chloroform was not used, the patient remaining quiet and obedient. Re inserting my hand into the vagina I placed the first and second fingers on the presenting surface of the placenta and, fixing the body of the fœtus externally with my left hand, with very slight resistance I tore through the placenta and, passing all my fingers through and widely enlarging the tear to give room, I felt the head presenting and strongly forced down by uterine action *a tergo* Changing hands, and dismissing all ideas of attempting podalic version, I rapidly applied my forceps and delivered the fœtus exactly three and a half minutes from taking up the first blade bleeding ceasing for the first time when traction commenced. Passing up my hand without any delay as the child's legs escaped I removed the placenta, firmly compressing the uterus with my left hand. The placenta came away in the hollow formed by my fingers and the membranes dragged after Then two hot intra-uterine douches of solution of izal were given and with the uterus contracting well no further hæmorrhage occurred.

The child was as was fully expected, dead and of apparently quite full weight and size The placenta was very large, thick, and soft, with the aperture made by me for the passage of the hand and fœtus almost exactly in the centre, judging by the fairly equal thickness of its substance forming now the circumference of the aperture. Its and pain in both temporal regions rapidly followed by œdematous swellings of the size of an orange, the next day there was no trace of these swellings beyond soreness at their site

From this date (the 3rd) there followed a rich abundance and variety of symptoms. From hour to hour, not merely from day to day, the clinical picture would change in a manner which defies description but which soon reduced the boy's attendants to a state of stolid but sympathetic expectancy and the patient himself to complete indifference. He seldom spoke throughout his long illness and even his monosyllabic utterances were accompanied by tears. In the course of 24 hours ugly swellings would appear and disappear, a dozen joints would be racked with pain in rapid succession, and the surface of the body would exhibit a whole atlas of skin diseases Simple erythema and purpura, urticaria, and erythema exudativum in all its varieties, cropped out and disappeared for week after week in disheartening fashion, blushes and spots, stony nodes and nodules, and enormous papules presenting themselves and vanishing one after another or in groups, but always irregularly in order and seat.

On the 4th there was occasional colic, on the 5th the most prominent features were œdema of the right upper eyelid of the size of a hen's egg, and in the evening return of the colic and vomiting, and severe pain in the elbows, wrists, and ankles, while both cheeks swelled suddenly, and erythema nodosum and purpura contended for supremacy in the limbs Purpura was triumphant on the morning of the 6th and the œdema was transferred from the cheeks to the forehead as though a variety of grotesque distortions of the features were the object, in the afternoon the buttocks were covered thickly with erythema papulatum. But the colic remained the most anxious symptom up to March 8th when it subsided in favour of pain all over the back, and this gave place in turn to pain, œdema, and tenderness of the left side of the trunk, the left thigh, knee and hand, and both legs, causing inability to move The patient was able to move comfortably once more by 9 30 P M on the 9th and he had no swelling save over one knee and one shoulder, and he was able to sleep well. At 1 A.M on the 10th he awoke with great abdominal pain and vomiting resulting in an alarming collapse which caused several anxious hours and required active measures By midday the colic had gone, but a copious purpuric rash had appeared on the face and elbows. From the 12th to the 15th the colic decreased, the flying pains and swellings continued until the 13th, and the only fresh rash was purpuric on both cheeks, the left knee, arm, and hand. The 14th was the first day that could be called satisfactory, the patient felt better, there were no pains or swellings, and the skin affection was limited to small crops of purpura. At 8 A.M on the 15th he was desquamating "all over," but by 1 P M his arms were thickly covered with purpura from shoulder to wrist. From this date until the 19th no new features arose, although the old symptoms of pain, swelling, and rash rang the changes on the joints and the different areas of the body, but with less vigour On the 19th for a brief period there were no pain, no colic, no new rash, a clean tongue, and a normal temperature in the patient, and in his attendants some hope of permanent improvement, when suddenly his flushed face drew attention to the pulse and temperature. Without apparent cause the pulse had risen to 104 and the temperature to 99 4° F, there were no abnormal cardiac signs. Up to this time the pulse had been the one cheerful feature, steady at 80 and rarely up to 90, and of good character, while the temperature had never exceeded 99° In the next few days the temperature rose slowly to 100 4° of an evening and 100° in the morning, while the pulse rate varied day and night between 120 and 130 On the 22nd the old symptoms took a new lease, colic and purpura, urticaria, œdema, and erythema, sudden and vanishing pains and swellings, once more perplexing us. On the 27th it was noted that the pains had left the region of the great joints and were affecting only the hands and feet, the axillæ and popliteal spaces, and the muscles of all the limbs. On the 28th there was actually no pain, swelling, or rash, only vigorous desquamation once more, but the increased pulse-rate and temperature warned us not to draw encouragement again from the suspension of the original symptoms The patient had a restless night, at 11 A M. on the 29th the pulse was 136 and the temperature was 99 4° and for the first time a loud systolic murmur was detected in the mitral area without any increase of cardiac dulness The cardiac condition now became the chief anxiety, there was, from this time, no return of the original symptoms except that the skin eruptions, especially the purpura, recurred every night for several weeks. It was interesting to observe that an erythematous blush could be produced at any time on any portion of the chest and abdomen simply by letting the patient know that one's attention was directed to that portion. The pulse rate fell slowly to about 106 by April 26th, on which day the temperature reached normal. The cardiac dulness remained unaffected. By May 4th the pulse was under 100 and on the 27th he was able to watch the school sports from his window, although he paid for the pleasure by a large crop of purpura on his legs and a slightly raised temperature—90 days after the onset of his illness, but small crops of purpura were not uncommon five months after the date of onset of his illness. The convalescence was marked by a gradual lessening in intensity of the cardiac murmur, encouraging a hope that it would ultimately disappear, but once more a new development retarded recovery Scarcely had he begun to use his legs when distinct, but happily not severe, chorea set in, the head, neck, and upper extremities, as well as the face, being affected mostly This condition persisted for several months but did not become serious, indeed, the boy was able to make a voyage to South Africa during the winter I have been unable to obtain a report as to his present condition, but he is said to be well although "nervous" as before

During the illness examination of the blood gave no information Frequent examinations of the urine detected no renal mischief During the first three weeks of the illness the total daily flow of urine was diminished more than there appeared reason for, it averaged, during that period, 18 ounces and ranged from nil to 29 ounces per diem. No benefit was obtained from the use of salicylates or any of the numerous drugs selected out of recommended remedies. Henoch's recommendation of icebags to the abdomen for the colic was of no avail. Careful nursing and feeding, together with palliative treatment of symptoms as they arose—a proceeding which often recalled the carpenter's estimate of the prospects of the seven maids with seven mops—was the method of treatment employed in this case.

No doubt the case presented a curious jumbling up of the symptoms of "Henoch's purpura" and "purpura rheumatica" with additions. The transient earache on Feb 23rd has been suggested as a possible source of septic infection The suggestion is incapable of proof or disproof. Whatever the poison it appeared to act upon the nervous system.

The case differed from those described by Henoch as follows (1) In its more continuous nature, there were no "intervals of several days or weeks or even of a year" (Henoch), (2) in the prominence of skin eruptions other than purpura, and of what can only be called "flying œdema"; (3) in the cardiac complication[2], (4) in the chorea, and (5) in the diminished daily flow of urine.

I had the advantage of meeting Dr H. P Hawkins in consultation over this case.

Florence.

A CASE OF APPENDICITIS WITH GENERAL PERITONITIS

By W GREENWOOD SUTCLIFFE, F R.C S. ENG,
HONORARY SURGEON TO MARGATE COTTAGE HOSPITAL AND THE ROYAL SEA BATHING HOSPITAL, MARGATE.

RECOVERY of cases of this gravity being sufficiently rare as compared with the small mortality attending operations where the damaged part is only slightly shut off, the details of this case may be worth putting on record.

The case appears to have begun on Oct. 24th, 1902, the patient, a girl, aged 20 years, being seized on that night with violent abdominal pain which was treated in the usual domestic manner without medical advice by the application of hot fomentations, with the result that the pain subsided next day, and a similar attack having occurred 12 months before which had cleared up satisfactorily it was thought that the trouble was practically at an end. The patient was able partially to go on with her housework, she, however, remained constipated and slight pains in the

---

[2] Compare a case of purpura described by Dr C W Buckley, THE LANCET July 20th, 1901 p 132.

the apex beat was diffused. There were no increase in the superficial cardiac dulness and no bruits The liver dulness commenced at the upper border of the sixth rib in the nipple line On inspection the abdomen was found to be deeply jaundiced Distension was noticed to the right of the umbilicus. On palpation to the right of, and extending for two or three inches below the level of, the umbilicus was a tender, elastic, tense resistance, roughly triangular in shape, merging above and on either side of its base with a more solid resistance, presumably the liver On percussion the above regions were both dull. The physical signs thus pointing to some obstruction of the common bile duct exploratory laparotomy was advised.

On Dec. 6th Dr Hatton made an incision in the linea semilunaris on the right side over the swelling and on opening the peritoneal cavity he discovered a much distended gall bladder, bearing signs of an acute local inflammatory condition and adherent above to a portion of great omentum. Cellular blanket cloth swabs having been packed around the lower and outer aspects of the gall bladder, an incision was made into it and a quantity of bile, at first purulent but later almost normal in character was evacuated. The cavity of the gall bladder was then found to be full of smooth small faceted calculi, averaging about the size of a large pea, of which 449 were removed. The gall-bladder was then sutured to the abdominal parietes and a drainage-tube and iodoform gauze-plug were inserted, the upper portion of the wound was closed with silkworm gut sutures. Owing to the length of the operation it was not deemed advisable to explore the gall-ducts at this time.

The patient bore the operation well and was anæsthetized with ether The after progress was very satisfactory, the jaundice lessened and disappeared. The tube was removed on Dec. 8th and the stitches on the 16th. Two more calculi of small size were passed, one on the 12th and the other on the 27th, bringing the total up to 451. The biliary fistula slowly closed normal bile being passed but lessening gradually and on the patient's leaving the infirmary on Jan. 12th, 1903, all that remained was a button of granulations with slight exudation of bile.

Stoke-on Trent.

A CASE OF COMPOUND COMMINUTED FRACTURE OF THE SKULL WITH HERNIA CEREBRI, OPERATION, RECOVERY

BY LLEWELYN LEWIS, M.R.C.S ENG, L.R.C P LOND

A BOY, aged 11 years was seen at his home at 11 30 A.M. on April 3rd, 1902. The mother stated that he had been kicked by a horse one and a half hours previously and that he had lost a tremendous quantity of blood. Previously the boy had been healthy and strong The father of the boy was a miner living in a small cottage of two rooms. The family history was good. When first seen the boy was lying on a settle. His face was blanched and blood was running from the right side of the head above the ear. He was in a collapsed condition and unconscious The pulse was very small.

On examination a lacerated wound was found, one inch in length, situated two and a half inches from the root of the zygoma, four inches from the middle of the bregma, four and a half inches from the middle line of the forehead, three and a half inches from the upper edge of the mastoid process, running horizontally, the centre of the wound being in a line one-eighth of an inch in front of the external auditory meatus Brain substance was oozing out Palpation revealed a compound fracture of the skull, the lower part of the bone being driven in and the upper edge of the bone projecting

The hair was shaved around the wound and the scalp was thoroughly cleansed with a 1 in 2000 solution of biniode of mercury and dressed with antiseptic wool. His parents were advised to remove him to the hospital and the seriousness of the case was pointed out to them. Up to this time the history is as given to me by Dr W Evans who was then assisting me in my practice On the following morning a message was received by me asking that something might be done for the boy as the mother would not allow him to be taken from home. At 1 P.M. (27 hours after the accident) the boy was seen and he was then in the same position and condition as on the previous day At 5 P.M. (31 hours after the accident) Dr Evans and I saw him and there was no difficulty in concluding that the case was one of compound fracture of the skull with protrusion of brain matter The boy was at this time in bed in the one living room of the house. He had to some extent recovered consciousness but was very dazed and looked ill He was at once put under an anæsthetic and the right half of the scalp was shaved and made as aseptic as possible. A semicircular incision was made through the scalp covering the area of injury On reflecting this flap more brain matter was seen to be oozing out of the cranial cavity and it was seen that the fracture was comminuted and that the posterior half was forced down and its edge deeply driven into the brain. The anterior part of the fractured portion was also broken up into several pieces some being forced into the brain. Being unable to remove the fragments of bone a trephine was applied to the sound portion of the skull on the upper edge of the fracture and an almost complete circle of bone was removed. A lever was then inserted under the depressed fragment, but as this did not enable me to remove it, a strong polypus forceps was used and the bone at the posterior of the fracture was wrenched out and raised above the level of the skull. In endeavouring to replace this it was found that the portion was now too broad to fit into its original place, by the loosening of the suture between the parietal and squamous portion of the temporal bone, the fragment was therefore entirely removed and this, with the other fragments, was placed in a normal saline solution at a temperature of about 100° F On further examination of the parts portions of brain matter were discovered to be so injured that it was deemed necessary to remove them and this was done by the aid of scissors. The brain and surrounding parts were then thoroughly cleansed with a 1 in 60 solution or phenic acid, the dura mater was brought together and the pieces of the skull were then sawn into smaller ones and filled into the space like tessellated pavement. A drainage-tube was passed down to the fracture, the scalp was brought together with fishing gut sutures, and the whole was dressed with perchloride wool

By the time we had washed ourselves and the instruments the boy had recovered consciousness and from that hour his intellect has been perfectly clear His temperature did not once rise above normal and with the exception of a little swelling over the left eye, the recovery was uninterrupted. The drainage-tube was removed on the fourth day and the whole wound quickly healed by first intention. The skull is now solid and all the pieces of bone have united to each other There was on no occasion any symptom of paresis in any organ or muscle and the pupils remained normal throughout and responded to light and accommodation His hearing was not in any way impaired. There has not been any symptom of brain trouble since and the boy is as formerly

The following three points are worthy of consideration – (1) the recovery in a most insanitary environment, the room in which the lad was lying being the only living room of a family of nine, the work of the household being carried on all the time, (2) the absence of any symptom of impairment, either mentally or physically, and (3) the excellent union of the sawn particles of bone which were immersed in saline solution for a period of not less than one and a half hours. From measurements taken it is assumed that the region injured was part of the temporo-sphenoidal lobe.

Neath.

LONDON TUBERCULOSIS SANATORIUMS — At a meeting of the Metropolitan Asylums Board on Feb. 7th letters were read from the Shoreditch, St. Marylebone, Paddington, and Stoke Newington borough councils stating that they agreed with the suggestion of the Kensington borough council that the Orchard and Joyce Green small-pox hospitals should be set apart for the treatment of tuberculous persons Some months ago the Bermondsey borough council, after circularising the other councils of London on the same subject, found that ten were in favour of sanatoriums being provided by the Metropolitan Asylums Board five approved of the principle of the need for the open air treatment of tuberculous patients but were not agreed as to the authority which should make the provision, and 11 remained indifferent On that occasion the Board decided to wait until the borough councils came into line and a year was allowed for that purpose. At the meeting on Feb. 7th, however, the letters gave rise to some discussion and notice of motion was given that the whole subject be reconsidered at the next meeting of the Board.

apparently largely spread-out attachment to the uterine surface doubtless accounted for the edge not being felt by the passage through the os of two phalanges of my finger The woman was not blanched or exhausted to the extent which might have been expected and had borne the whole of the most trying operation bravely, which was much more quickly performed than might appear from its description in writing

In this case a departure was made by me from the instructions of text-books—to rupture the membranes at the edge of the placenta and to perform version by grasping the first foot met with. But the placenta was one of the very largest I have ever seen and there was my previous experience of her confinements to guide me—namely, that there was no pelvic deformity or flattening, the os was usually quickly dilated, an unrepaired perineum existed, and that the patient possessed great courage and self control—hence I preferred to perforate the placenta and, finding the head low down in the pelvis with firm uterine contractions, extracting rapidly with forceps to attempting podalic version.

Recovery was uneventful, the temperature and lochia were normal, and all symptoms of anæmia quickly disappeared with good food and nursing

Husbands Bosworth, Rugby

NOTE ON "RELAPSES" IN SCARLET FEVER

By A. BANKIER SLOAN, M D GLASG,

ASSISTANT MEDICAL OFFICER METROPOLITAN ASYLUMS BOARD FEVER HOSPITALS, AND LATE ASSISTANT MEDICAL OFFICER TO THE RUCHILL FEVER HOSPITAL, GLASGOW

MY attention was attracted by a note in THE LANCET of Nov 29th, 1902, p 1458, on a Case of Scarlet Fever followed by an interesting Relapse, by Dr Henry Fraser On looking up the annual report of the Metropolitan Asylums Board for 1901 I find that "relapses" occurred in 154 out of 14 143 cases of scarlet fever, or in 1 09 per cent. That "relapses" do occur, I think, is admitted by practically all competent authorities, and I scarcely think that Dr Fraser will find "many" men who have seen much hospital work deny the fact Personally, from my own limited experience I have no doubt that they do occur As it happens I have at the present time two typical cases under my care.

CASE 1.—A girl, aged five years, was admitted into the Western Fever Hospital on Oct 7th, 1902. She had sickened on the 6th and the rash had appeared on the following day When admitted the tongue was moist, clean, and red and showing prominent papillæ, the mucous membrane of the palate and fauces was injected and the tonsils showed pultaceous exudate, there was a typical, general, punctate erythema, the temperature was 99° F On the 10th right otorrhœa began and on the 20th it was noted that she was desquamating typically On Nov 7th, after having been out of bed for some days, she developed a general, bright, punctate erythema, her temperature was 99 6°, her throat was distinctly injected and her tongue was red. On Dec. 4th (being the sixtieth day of the disease) I specially examined her and found that she was going through a second typical general desquamation.

CASE 2.—A boy, aged four years, was admitted into the Western Fever Hospital on Nov 4th, 1902. The history was that four weeks previously to admission he had suffered from vomiting and diarrhœa, and that from that date up to the time of admission he had had rhinorrhœa On admission he was desquamating freely on the hands, he had excoriated nostrils and a profuse rhinorrhœa; the throat was slightly congested He was well and had been out of bed for some days when on Dec. 2nd his temperature rose, he developed a bright, general, punctate erythema, the throat became swollen and injected, and the glands at the angle of the jaw were tender and enlarged The maximum temperature was 102 4° F The purulent rhinorrhœa had recurred and his throat was now rather "dirty"

Both these cases I consider undoubted relapses I have also under my care another case which I look upon as a "relapse," but as the original desquamation was not profuse I do not detail it I do not care for the term "relapse" in these cases as I have the feeling, although it may be entirely erroneous, that the majority of these cases occur through re infection from without and not from auto-infection. On this account I prefer the term "second attack." Doubtless, however, true relapses (cases due to auto-infection) do occur I should like very much to know if "relapses" are often seen in general practice, as I think that their absence would go a long way to prove that the majority of the cases under discussion are "second attacks" and not relapses in the true sense.

In connexion with this subject I should like very briefly to refer to another class of cases seen occasionally in hospital which differ from the cases above discussed in that they do not desquamate after the first attack. They are what one might call "mild scarlatinal infections" as against scarlet fever Such cases are admitted with a history of slight sore throat, transient rash, and slight malaise. On admission to hospital they usually show a normal temperature They do not desquamate. However, if put in a scarlet fever ward they develop scarlet fever, not immediately after admission, but about three weeks later The following is a case in point

CASE 3—A boy, aged five years, was admitted to the Western Fever Hospital on Sept. 1st, 1902. He had a slight shivering on August 31st and slight sore-throat. On Sept 1st, the day of admission, a rash was said to have been seen On admission there was no rash, the temperature was 99° F, the mucous membrane of the fauces was congested, and the tongue was coated and had prominent papillæ He did not desquamate at all although watched carefully On the 27th he developed a typical attack of scarlet fever, having a bright rash with a temperature of 103° He subsequently desquamated freely In connexion with this case I would specially point out that a sister of this patient was admitted on the same day as he was and that she desquamated typically in the ordinary course The facts that the boy's sister had scarlet fever and that he did not develop scarlet fever in the ward till three weeks after admission point to his having acquired a certain immunity through the first transient illness and if so it must have been of the nature of scarlet fever

Fulham S W

A CASE OF AN UNUSUAL NUMBER OF GALL-STONES, CHOLECYSTOTOMY, RECOVERY

By C A S RIDOUT, M B, B S LOND, L.R.C P LOND, M R.C S ENG,

HOUSE SURGEON TO THE NORTH STAFFORDSHIRE INFIRMARY STOKE ON TRENT

THE following case is one of considerable interest owing to the great number of gall stones removed at one operation from the gall bladder I can find no record of a greater number having been similarly removed and therefore I venture to report the case.

A married woman, aged 43 years, was admitted into the North Staffordshire Infirmary on Dec. 3rd, 1902, under the care of Dr G Stokes Hatton, senior surgeon to the infirmary, suffering from abdominal pain and jaundice, As history it was stated that the patient was quite well until five weeks previously when she was seized with a severe attack of pain at the bottom of the back and in the right hypochondrium, accompanied by faintness, sweating, and sickness The attack lasted acutely for three days but she had had pain off and on ever since and from Nov 29th she had been jaundiced—i.e., the jaundice was first noticed four days previous to admission. She stated that she had had many previous attacks of pain of a similar nature and that she had been losing flesh for the past six months The patient was the mother of two children and she had had no miscarriages and she menstruated regularly

On admission, the patient was a thin faced woman, deeply jaundiced, both skin and conjunctivæ being markedly affected, the tongue was furred and dry and the skin was dry The pulse was 120 and feeble, the respirations were 28 and quiet, and the temperature was 102° F and tending to remit The urine was acid, with a specific gravity of 1014 and a faint trace of albumin, it contained no sugar and was deeply stained with bile The bowels were opened by aperients, the fæces were clay coloured. The lungs were natural, the heart's action was feeble, and

Semon's paper in 1895. He considered that the bacteriological examination in these cases was of special importance. This class of case was severe and unless promptly dealt with often proved fatal. The meaning attached to the word 'pathological identity' was of great importance. In Mr de Santi's cases examination had shown that the same micro-organism was present in each case, but he considered that similar clinical conditions might be produced by various micro-organisms. The late Professor Kanthack had shown that ulcerative endocarditis might be due to a variety of organisms; clinically these cases were identical; pathologically they were not identical. He referred to three cases of acute infection of the throat in children which clinically had the aspect of diphtheria, but bacteriological examination showed that they were due to staphylococcic infection and not to the diphtheria bacillus.

Sir DYCE DUCKWORTH said that he had always considered that there could be all degrees of inflammation, from a slight inflammation to the severest forms of Ludwig's angina, produced by the various forms of streptococcic infection. He advocated the use of mixed sera in the treatment of these cases since it was always uncertain what variety of streptococcus was being dealt with. He had never seen any harm come from the injection of such sera.

Mr E. B. WAGGETT pointed out that all of the cases recorded by Mr. de Santi were men in the prime of life. His own experience led him to believe that the disease usually attacked young men in good health. He related the case of a young man who during the first three days of illness had sore-throat but no symptoms of severity; on the fourth day, however, he had acute swelling of the fauces and uvula with swelling of the neck. Pus was evacuated by an incision in front of the sterno mastoid and the patient made a good recovery. He advocated immediate operation in all such cases. The condition he believed, depended on the virulence of the organism.

Dr J. DUNDAS GRANT said that the symptoms of this affection were constitutional as well as local and that in some cases the local throat symptoms might be slight when the constitutional symptoms were most severe. The aspect and the voice of these patients often suggested the presence of a peri tonsillar abscess, but on examination no such swelling could be detected and he considered that that symptom was of great diagnostic value. He related a case of rapid death from laryngeal obstruction in such a condition. He asked Mr de Santi if he had any evidence showing that there was any danger in the use of anti streptococcic serum. He thought that great relief was often obtained from the use of ice and he had never seen any harm result from its use.

Dr F. J. POYNTON said that to distinguish between the varieties of streptococcus pyogenes it was necessary to employ other methods than cultivation and the consideration of morphological characters as, for example, experimental injections and such bio-chemical tests as Marmorek's filtration test investigations on hæmolysis bacteriolysis, agglutination, and specific immunity. If the unity of the streptococcus was accepted in the present state of knowledge he thought that the result would be to attempt to explain clinical difficulties by referring them to an insecure bacteriology. He would accept for argument's sake this unity and turn to the explanation that was then given of the differing clinical results. They were explained by (1) the number of organisms that gained access, (2) the intensity of the virulence, and (3) the resistance of the individual. But were these sufficient? He thought not, and detailed a recent investigation he made on this subject with Dr A. Paine. A student pricked his finger at a post-mortem examination on a case of suppurative peritonitis; he developed alarming symptoms and was threatened with acute septicæmia. Fortunately his resistance proved successful though an abscess developed in the axilla; from the pus they obtained an organism which might be justly called the streptococcus pyogenes. At the same time they isolated a streptococcus from a case of malignant endocarditis. Both these they placed in the same medium, a slightly acid one (not the most favourable for maintaining the virulence). Thence they transferred them to blood agar. Two rabbits living under the same conditions and from the same litter were inoculated intravenously with these results. A small dose from the septic case produced death in 24 hours with septicæmia; a large dose from the case of endocarditis produced death in five days from malignant endocarditis of the mitral valve, the specimen of which he showed. Wherein lay the explanation of the different results? Not in (1) the number of organisms injected, for the fewer organisms produced the most fatal result; probably not in (3) the nature of the resistance, since the two rabbits were much alike; but very plausibly in (2) the difference of virulence. They carried on the original cultures in the acid medium for three weeks and repeated the investigation. One rabbit was injected intravenously from the septic micro-organism and one subcutaneously and two more in the same way with the organism from the case of endocarditis with these results. The two rabbits injected with the septic micro-organism died on the second and tenth day respectively from septicæmia; the rabbit injected intravenously with the other microbe died on the fourteenth day from malignant endocarditis of the aortic and mitral valves; that injected subcutaneously developed a firm nodule at the point of inoculation which disappeared and the animal recovered. They waited another three weeks and again repeated the investigation and this time all the animals recovered. He thought then that factor (2)—the intensity of virulence—had been altered in each case to practically a zero. He believed there was a fourth factor—viz., a tendency inherent in micro-organisms to produce special poisons, a specific toxicity which had to be reckoned with in all investigations on the unity of the streptococcal group.

Sir FELIX SEMON said that when he brought forward his paper in 1895 it had met with considerable opposition and he believed that arose, firstly, because the diseases which he had classed together had always been considered so entirely different clinically; secondly, because he had used the words "pathological identity," meaning thereby the same morbid process and not the identity of the micro organism; and, thirdly, because of the uncertain state of bacteriology at that time. He believed that any organism of the pyogenic group could produce this affection. He considered these cases of the greatest practical importance and since 1895 he had seen five cases. He agreed with Mr Waggett in believing that the disease usually attacked individuals in good health, but they often had had sugar in the urine either at the time or at some time previously. He described the five cases in three of which death occurred, while in the other two recovery took place. The prognosis in the severer cases was very grave. He was in favour of using anti streptococcic serum, but as he believed there was a specificity in the sera and that the disease might be caused by any one of the pyogenic groups the sera would not be equally beneficial in all cases.

Mr DE SANTI replied.

MEDICAL SOCIETY OF LONDON.

Discussion on the Treatment of Epilepsy

A MEETING of this society was held on Feb 9th, Mr A. PEARCE GOULD, the President, being in the chair.

A discussion on the Treatment of Epilepsy was opened by Sir VICTOR HORSLEY and Dr J. S. RISIEN RUSSELL.

Dr RUSSELL commenced by remarking that he would confine his attention to idiopathic epilepsy—i.e., that which arose without apparent cause. The ideal to be secured was a plan of treatment which was based on a knowledge of the etiology and pathology of the affection and which aimed at removing or antagonising the cause. He would first consider whether any researches had supplied evidence that could be regarded as positive or reasonable proof of the etiology and pathology of idiopathic epilepsy. The brains of epileptics showed degenerative changes, but there was as yet no unanimity of opinion as to how far these morbid changes were responsible for the clinical manifestations of epilepsy and how far they were merely evidences of the destructive effects of the storms. Of the various theories advanced to explain the occurrence of epilepsy, that which supposed that epilepsy resulted from an auto intoxication had received most acceptance, though it could not be said to be proved. Some considered that the affection was due to the incursions of micro-organisms, but this view was equally without satisfactory proof. Indeed, in spite of all the researches that had been made they were still in ignorance of the essential cause of epilepsy. Nevertheless, treatment had been initiated which presupposed that epilepsy was due to the action of some poison which reached the nerve elements by way of the blood stream. In the hope of establishing immunity serum obtained from a patient with severe epilepsy had been injected into another

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Four Cases of Acute Septic Inflammation of the Throat, with Bacteriological Report

A MEETING of this society was held on Feb 10th, Mr ALFRED WILLETT, the President, being in the chair

Mr P R. W DE SANTI read a paper on Four Cases of Acute Septic Inflammation of the Throat, with Bacteriological Report. He said that the present paper was a sequel to a contribution by Sir Felix Semon to the Fellows of the Royal Medical and Chirurgical Society on April 23rd, 1895, and entitled ' On the Probable Pathological Identity of the Various Forms of Acute Septic Inflammations of the Throat hitherto described as Acute Œdema of the Larynx, Œdematous Laryngitis Erysipelas of the Pharynx and Larynx, Plegmon of the Pharynx and Larynx, and Angina Ludovici." Since the publication of that paper he had determined to keep careful records of any cases of acute septic inflammations of the throat that might present themselves to his notice, particularly as to their bacteriology Since 1895 he had been able to observe four such cases and the notes of these cases were given in their order of ascending severity Case 1 was that of a man, aged 48 years, who came under the care of Mr de Santi at Westminster Hospital in 1899 with a deep-seated and extensive abscess of the right cervical region and a discharge of pus from the right external auditory meatus Pressure on the abscess caused pus to well out of the external auditory meatus, a perforation of the deep digastric aspect of the right mastoid was diagnosed and the mastoid abscess in the neck was opened up and the diagnosis was verified The patient went on well for nearly three weeks when he suddenly developed cutaneous erysipelas of the left cheek, this rapidly spread to the rest of the face and neck on the left side and then across the midline to the right face and neck, he also had extensive patches over the back down to the lumbar region Soreness of the throat was complained of and examination revealed a bright red swelling of the posterior pharyngeal wall, soft palate, and uvula Cultures from the throat showed streptococcus pyogenes and a few staphylococci 10 cubic centimetre doses of anti streptococcic serum were given three times during the ensuing 22 hours when the rash had almost entirely disappeared, the throat condition cleared up, and the temperature had fallen to 99 2° F The patient made an excellent recovery Case 2 was that of a man who complained of sore-throat and swollen cervical glands Examination revealed intense redness and swelling of the right tonsil, the whole of the soft palate and uvula, and dark red swelling of the posterior pharyngeal wall, there was also slight œdema of the epiglottis The temperature was 104 6° F and his general condition was bad There was no history of anything likely to cause the throat trouble The urine, heart, and the lungs were normal. The patient refused admission to the hospital Swab cultures from the throat showed streptococcus infection The further history of the case was unknown Case 3 was that of a man who complained of sore throat, loss of voice, and dysphagia of from two to three days' duration Examination revealed acute gangrenous inflammation of the lower half of the uvula and acute œdematous inflammation of the soft palate and to a less degree of the tonsils. There was also extensive œdema of the left ary-epiglottic fold. The patient's general condition was bad, the temperature was 101 2° F He was admitted to hospital Swab cultures showed the presence of the streptococcus pyogenes. A dose of 20 cubic centimetres of anti streptococcic serum was at once injected and pure carbolic acid was rubbed into the uvula, five hours after the injection the patient, who could not swallow before, was able to do so and felt much better in himself No further injections were necessary and the patient made an uneventful recovery Case 4 was that of a man aged 21 years who was admitted to the hospital with sore throat followed by a swelling in the neck. When first seen the patient was partly unconscious, had great pain and difficulty in swallowing, and great pain over the heart. The temperature was 101 4° F, having been 103° during the night. His general condition was very bad Examination showed acute septic pharyngitis, deep glandular inflammation, and pericarditis. The mucus from the throat and the fluid evacuated from the glands showed on examination both in cover glass specimens and upon cultivation, mainly streptococcus pyogenes. 10 cubic centimetres of anti streptococcic serum were injected three times during the first 24 hours and once during the next 24 hours The effect was remarkable, the patient beginning to rally at once He made an excellent recovery Of the above four cases the first would be called by some "cutaneous erysipelas of the pharynx,' the second "œdematous" or possibly 'plegmonous pharyngitis," the third "gangrenous uvulitis," and the fourth "phlegmonous pharyngitis" Yet they were all of the same nature—namely acute septic inflammations of the throat—in all the streptococcus pyogenes was present, and in three out of the four treatment by injections of anti streptococcic serum was successful. In Sir Felix Semon's paper four objections were advanced by him as likely to arise with regard to his views on acute septic inflammations of the throat and neck. Firstly, ' that he had given no proof that the milder cases in his series were really of septic origin and that they might well have been simple catarrhal inflammations." As no bacteriological examination was made of his cases it was open to anyone to deny the certainty of their septic origin Of the four cases here recorded No 1 was certainly of a mild, local character and No 2 fairly so—at all events, it was analogous to No 4 in Sir Felix Semon's series—yet in both these cases streptococcus pyogenes was present and the clinical symptoms were far greater than in simple catarrhal inflammation The bacteriological examination of these cases tended to prove, therefore, that these milder cases were of a septic nature and this was strengthened by their clinical character and course. Secondly, "that the different localisation in Sir Felix Simon's cases—namely, whether originating in the pharynx, larynx, or cellular tissue of the neck—spoke against their being identical." This objection did not hold good The different localisation of these septic inflammations of the throat depended on the resisting powers of the parts attacked, an accidental breach of surface or a pre-existing condition of catarrh rendering the parts more susceptible to infection Thirdly "that the variations in the fever curve in Sir Felix Semon's individual cases also seemed to point in the direction that this fever was caused by different and not identical processes" Mr de Santi considered that the temperature in these cases was bound to vary as in other diseases according to the resulting inflammation, whether œdematous suppurative, or gangrenous, and according to the amount of poison absorbed He did not, therefore consider that objection No. 3 was valid Fourthly, "that the fact that the exudation sometimes being of a serous and sometimes of a purulent character most powerfully combated the view that these inflammations were identical in nature' This, perhaps the most important objection, had to be combated mainly from a bacteriological point of view The present-day opinions were (1) that the streptococcus pyogenes and other pyogenic cocci could produce apart from purulent inflammations all other forms of inflammation such as serous, fibrinous, hæmorrhagic, and gangrenous inflammation, and (2) that the variety of inflammations resulting depended on (*a*) the quantity, (*b*) the virulence of the organism introduced into the system, and (*c*) the resisting powers of the subject inoculated. It seemed, therefore, that the conclusions were amply sufficient to account for the differences in not only the fever curve of these acute septic inflammations of the throat, but also for the differences in the kind of inflammation resulting—namely, œdematous, purulent or gangrenous He therefore entirely agreed with Sir Felix Semon's conclusions as regards the probable pathological identity of these acute septic inflammations of the throat and thought that the four objections referred to could be refuted in the light of the four cases brought forward by himself He had adduced evidence of the presence of the streptococcus pyogenes in all his cases and of the identity clinically of his series with that of Sir Felix Semon, and had stated the excellent results that had occurred from the injection of anti streptococcic serum As regards the treatment of acute septic inflammations of the throat with anti streptococcic serum he wished to point out that unless the streptococcus pyogenes was found it would be worse than useless—indeed, dangerous—to give these injections.

Dr DE HAVILLAND HALL said that he had the pleasure of opening the discussion which took place on Sir Felix anatomy of the condition was discussed and various allied conditions were demonstrated. It was shown that *Drüsen* were not ordinary colloid bodies such as are found upon the choroid, though these too might occur near the disc. Exudates similar to the hyaline nodules might become metamorphosed into true bone as was frequently seen in the choroid in shrunken globes. The fate of exudates in the disc and in other parts of the eye and its dependence upon environment were discussed.

Mr J H. PARSONS read a paper on Primary Extradural Tumours of the Optic Nerve, with clinical and pathological notes of a case illustrated by lantern slides. There were 18 cases on record as compared with 102 primary intradural cases. The disease usually commenced before the age of 10 years and the prominent symptom was exophthalmos, the protrusion being most marked in the axis of the orbit. The failure of vision was slow, slower than with intradural tumours, and was accompanied by optic neuritis of the 'choked disc" variety, to be followed by post-neuritic atrophy Later changes in the eye resulted from lagophthalmos. In no case was the globe invaded by the growth Eight of the growths were undoubtedly endotheliomata, several having the characteristics of psammomata The fibromatosis present in most cases was a feature of importance. The growths were slow and of relatively low malignancy, giving rise neither to glandular dissemination nor to metastasis Considering this fact and that the point of danger was at the apex of the orbit Krönlein s operation, with retention of the globe, was indicated wherever possible.

Mr L. WERNER reported two cases of Tumour of the Optic Nerve operated upon by Krönlein's method, and referred to another under the care of Mr H. R. Swanzy The first case was that of a woman, aged 45 years, who had noticed swelling of the inner canthus for one year before coming under observation. When seen the left eye was two centimetres in advance of the right and directed downwards, there was no pulsation or bruit, and though the eye was blind the patient was unaware of it. The eye was anæsthetic, tension was normal, and there was marked optic atrophy seen through the clear media Tumour of the optic nerve was diagnosed and with the optic nerve was removed by Krönlein's method, the eye being left in its place. A semi circular incision with the convexity forwards, and extending to near the outer canthus, was made exposing the outer wall of the orbit The bone was removed as widely as possible by dividing it with a chisel at the fronto malar suture and just above the zygoma, extending the incision backwards to the spheno-maxillary fissure and turning the bony mass back with the soft parts. The tumour was then isolated and removed, there was a clear portion of optic nerve in front, but posteriorly the growth extended into the apex of the orbit and required removal piecemeal. There was some hæmorrhage, causing temporary protrusion of the eye ball after replacement of the flap No sutures were put in the periosteum and no drainage-tube was inserted. The lids, which were temporarily attached, became œdematous, but on removing the dressing on the fifth day union was complete and though anæsthesia of the globe persisted the eye assumed a normal appearance, and movements, except lateral, were free The tumour, inclosed in the dural sheath, was an alveolar sarcoma, the grouped cells being arranged concentrically, suggested endothelioma. The second case was that of a girl, aged 11 years, whose eye for 14 months had been prominent and divergent. The eye was removed with the growth, the inner aspect of the lid was scraped and the orbit was cleared out. The growth proved to be a myxosarcoma surrounding the nerve which had entirely degenerated. Krönlein performed this operation first in 1886 and published an account in 1889 It was not difficult and had many advantages. The wedge of bone freed should be as large as possible and the division of the outer orbital plate should be accomplished before completely freeing the anterior part to avoid splintering The risk was practically nil, of 73 cases one only had died. The limitation of lateral movement was temporary only and in cases where the nerve was not involved sight might be preserved.

Dr THOMAS SNOWBALL read a paper on the Formation of Bone in the Choroid Notes were given of a series of seven cases in which ossification had taken place in eyes that had become blind and shrunken as the result of old perforating injuries or long standing inflammation with or without perforation. In the choroid a chronic inflammation with plastic exudation was set up, leading to degenerative changes in the various layers of this coat, the outer pigmented stroma became more or less fibrous, the inner layers, the chorio-capillaris, and membrane of Bruch were to a large extent replaced by fibrous tissue which had become organised from the exudation poured out towards the inner surface of the choroid. In this fibrous tissue the bone had developed At the areas of bone formation the chorio-capillaris when present was never a continuous layer but was represented by only a few vessels here and there. The lamina vitrea when seen near the focus of bone was never found external to it This was contrary to the observations of Brailey, Fontan, and others, who described cases where the membrane of Bruch was seen as a distinct line external to the plate of bone In most of his own cases the bone formed a layer in the usual situation—namely, around the optic nerve entrance. In one case where colloid bodies were undergoing ossification, the bone in the choroid had evidently arisen independently of them and was a more advanced stage of development. In none of the cases was there a trace of sympathetic disease in the other eye. From a study of his own cases and those described by Knapp, Whiting, Legrange, and many others, it was concluded that ossification in the choroid arises most commonly in fibrous tissue developing in the chorio-capillaris and either replacing it or lying immediately external to it.

The following cases and card specimens were shown —

Mr L WERNER Coloboma of the Optic Nerve.

Mr F A C TYRRELL Congenital Malformation of the Lower Eyelids

Major M T Yarr, R A.M.C Changes in the Macular Region following Contusion of the Eye.

Mr E TREACHER COLLINS A Case of Favus of the Upper Eyelid

Mr W T HOLMES SPICER Sections from Nævus of the Orbit

Mr J H. FISHER Aneurysmal Dilatation of the Retinal Vessels in a boy suffering from Heart Disease.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

The Sequelæ of Typhoid Fever

A MEETING of this society was held on Feb 6th, Mr. RICKARD W LLOYD, the President, being in the chair

Dr SEYMOUR TAYLOR opened a discussion on the Sequelæ of Enteric Fever and their Treatment. He defined sequelæ as conditions occurring after the end of the febrile process when the temperature had been normal for two days and two nights After mentioning the difference in type of epidemics occurring in Great Britain and in other climates, he called attention to the fact that many patients stated that their health was much improved after an attack of typhoid fever Dr Taylor then analysed 56 cases of relapse and pointed out that in many cases a change of diet, starchy food or an enema or purge seemed to bring about the relapse, although in many cases no cause could be assigned Under respiratory sequelæ tuberculous disease was mentioned, latent trouble being frequently aroused to activity Laryngitis with necrosis might occur, leading sometimes to emphysema of the neck and a condition resembling Ludwig s angina As regards the circulatory system, thrombosis, nearly always of the lower limbs, was fairly common. The extent of thrombosis was often large and the clot might extend into the vena cava Dilatation of the heart, with valvular incompetence, was also a sequela. Nervous sequelæ were not uncommon, such as definite insanity or some moral obliquity Aphasia might occur and also peripheral neuritis. Besides constipation and meteorism peritonitis and perforation might be sequelæ, peritonitis being possibly started by bacilli in a gland or by infection from the appendix or from the gall bladder Perforation might be suspected when with a falling temperature the pulse becomes rapid, associated with the characteristic facies Sequelæ affecting the skin, subcutaneous tissues, or bones were such as noma, gangrene, and necrosis. These were not necessarily due to the intensity of the fever but to the condition of the individual.

Dr WILLIAM HUNTER took a wider view of the definition of sequelæ. He regarded them as complications which occurred apart from the ordinary course of typhoid fever and with

with a milder form of the affection, while in other cases serum obtained from a patient had been reintroduced on a subsequent occasion The knowledge that acute specific diseases exerted a favourable influence on the course of epilepsy had induced some observers to attempt to obtain artificially similar beneficial effects by the inoculation of epileptic patients with filtered cultures of streptococci and staphylococci, erysipelas toxin, or antitoxin None of these measures, however, had met with a degree of success which justified the belief that a successful plan of treatment lay in this direction. Dr Russell was obliged to admit that the bromides were still the most potent agents for the treatment of idiopathic epilepsy This form of treatment, to be successful, needed much attention to detail. A timidity that courted failure was too often evident in the way in which the drug was given. If bromide was to do good it must be given boldly and the physician, the patients, and their relatives must rid themselves of the usual prejudices against the drug Many of the ill effects that were attributed to the bromides were in reality due to the epilepsy and much that was legitimately ascribed to the bromides might be averted if the drug were given more freely in the early stages of the malady In this way there would be a better chance of arresting the epileptic attacks early and therefore it would not be necessary to administer the drug over a period of at least two or three years Dr Russell had not seen any special advantage gained by giving the mixed bromides of potassium, sodium, and ammonium and his custom was to give the potassium salt. Bourneville had so persistently advocated the use of bromide of camphor and such excellent results had been published from the Bicêtre Hospital that the preparation seemed worthy of a trial Whichèver of the bromide salts was used a single dose should be given an hour before bed time in nocturnal epilepsy and two hours before an attack was due, when the fits recurred about the same time in the day It sometimes became necessary to give the drug twice or even three times a day, but it was, as a rule, better to increase the single dose up to one drachm or more than to give it in divided doses several times a day Of medicinal adjuncts or substitutes for bromide in the treatment of epilepsy borax, belladonna, digitalis, and arsenic had most justified their use Nitro glycerine had been advocated by Sir William Gowers Flechsig's method of employing opium in large doses for several weeks and then giving large doses of bromide had little to recommend it A subcutaneous injection of morphia, however was one of the surest means of arresting the recurring attacks in the status epilepticus The risk of employing the drug was great and it was better to rely on hyoscine by subcutaneous injection or large doses of chloral by the rectum. Of the newer preparations such as bromipin, bromalin, or bromocoll, the first had been most extensively tried and had been favourably received. In considering what dietetic and other measures aided in securing success for the bromide treatment, the importance of prohibiting stimulants, including tea and coffee, was well recognised. These patients did best on a diet which contained only a small amount of meat The most important modification that had been introduced into the dietetic treatment of epilepsy during recent years was the exclusion of ordinary salt from the dietary but this had been anticipated by Dr J Hughlings Jackson 30 years before. By limiting the amount of sodium chloride given in the diet much smaller doses of bromide proved effective Attention should be paid to the arterial tension. Much might unquestionably be done to secure greater toleration of the bromide salts and to render them more effective in their action by attention to a number of details in the daily life of the individual. This was one of the ways in which epileptic colonies proved of such great advantage

Sir VICTOR HORSLEY, in his opening remarks, expressed the belief that epilepsy should really be regarded as a symptom, not as a disease He would classify epilepsy according to its causation into four groups 1 Idiopathic epilepsy in which there was no gross lesion This might be of localised (focal) or generalised onset, but neither of these classes was very suitable for operation. He had however, operated on five cases of the former Two of the cases had proved to be of organic origin. These showed that an exploratory operation might be justifiable in cases which had resisted medical measures 2 In Jacksonian epilepsy there existed always a gross lesion or a toxæmia. In traumatic cases of a Jacksonian type the convulsions might be generalised or localised In the former surgical measures were not by any means uniformly successful, in localised cases, however, trephining was very successful, particularly when the scar was in the so called motor area, it was less successful when the scar was in the occipital region and still less successful when it was in the frontal or temporo sphenoidal region. Cases of congenital focal epilepsy did fairly well when operated on in early childhood. Cases of neoplastic origin were, of course, very amenable to surgical measures The fits in such cases were not always localised, they might be so generalised as to resemble idiopathic epilepsy 3. Reflex epilepsy might arise from injury to a nerve, injury to the spine, or from traumatism (e g, those rare cases in which touching the head had been followed by fits) 4 In hystero-epilepsy no operation should be performed, though ovariotomy and other procedures had been employed by some.

Dr C E BEEVOR thought it was very difficult to trace a toxic origin of epilepsy, though the cortical cells were admittedly in a very unstable condition. He wished strongly to indorse the view that bromide could be administered with perfect safety over many years. It was not this drug but the disease which produced the mental deterioration One of his patients had taken bromide for 20 years without harm He generally gave the ammonium salt, but this was a minor point. The doses were best given thrice daily

Dr J A. ORMEROD agreed with the remarks made by Dr Russell and Sir Victor Horsley He referred to the advantages of borax as a change from the bromide Belladonna was useful for *petit mal* Digitalis and bromide were useful in cases of hystero-epilepsy The chief reason why bromide failed was the dose being too small He suggested the possibility of cyclical changes in the course of idiopathic epilepsy and advocated a study of the determining causes of fits, such as worms, undigested food, fright, anxiety, mental overwork, menstruation, or the advent of puberty

Dr T SEYMOUR TUKE referred to the mental symptoms which occurred in epilepsy and quoted a case in which the attacks disappeared after matrimony

Dr W ALDREN TURNER had collected statistics bearing on the relative merits of different methods of medicinal treatment Before the introduction of bromides, the late Sir Russell Reynolds, treating cases by means of silver and zinc, and basing his results on a period of four years' exemption from fits, had accomplished a proportion of cures amounting to 10 per cent., the late Professor Trousseau in similar circumstances had accomplished 13 per cent By the courtesy of his colleagues at the National Hospital for the Paralysed and Epileptic he had investigated 366 cases of idiopathic epilepsy treated by bromides, and basing his results on a period of nine years' exemption from fits the proportion of cures amounted to 10 3 per cent. In the latter series of investigations the period of exemption was much longer and pointed to the advantages to be gained from the administration of bromides and this coincided with Dr Turner's own experience of the disease.

Dr R L. LANGDON DOWN had found bromide of potassium most useful in major epilepsy, but in *petit mal* it was, he believed, harmful He did not, after trial, attach much importance to the exclusion of meat

Sir VICTOR HORSLEY and Dr RUSSELL replied

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

Hyaline Bodies in the Optic Disc —Primary Extradural Tumours of the Optic Nerve, Krönlein's Operation —Formation of Bone in the Choroid —Exhibition of Cases and Specimens

A MEETING of this society was held on Jan. 29th, Mr W LANG, the President, being in the chair

Mr A. STANFORD MORTON and Mr J HERBERT PARSONS brought forward a paper upon Hyaline Bodies (*Drüsenbildungen*) in the Optic Disc, with drawings and notes of two cases and lantern slides. Out of 42 cases recorded in the literature seven had retinitis pigmentosa, others were associated with injury, nervous disorders (from simple headache to chronic hydrocephalus and insanity) and chronic interstitial nephritis, but a large number of patients were normal, with normal vision The condition usually commenced in early life and was extremely chronic. In nearly all cases both eyes were affected but often unequally The prognosis was good. The pathological not go beyond the middle line There was loss of conjugate deviation of the eyes to the left. No other nervous phenomena were present The diagnosis at this time was paresis of the left internal rectus She could converge the eyes perfectly The third nucleus and the third nerve were apparently unaffected and the lesion was probably further down in the position of the sixth nucleus This nucleus innervates the sixth nerve and also indirectly the third nucleus of the opposite side, and consequently also the third nerve of the opposite side and thus also the corresponding internal rectus muscle When both the sixth nuclei act there is convergence of the eyes. There was evidently no affection of the pyramidal tracts and the diagnosis was thought to be an exceedingly limited lesion at the floor of the fourth ventricle, affecting the nuclei of both sixth nerves and the seventh nerve twisting round this nucleus Eventually the right eye became more prominent and the lateral movements of the eyeballs were entirely lost. The temperature began to rise, increased headache and vomiting and great pain at the back of the neck were complained of Shortly before death there were complete double paralysis of convergence and other symptoms of localised meningitis Up to the age of 15 years the patient had been fairly healthy, but the subsequent family history pointed to a possible tuberculous taint The necropsy revealed the presence of localised tuberculous meningitis at the base of the brain and a tuberculous tumour filling up almost the whole of the fourth ventricle. This tumour had nearly cut out the two nuclei of the sixth nerves and the facial nerve around it. Degenerated fibres could be traced upwards from the sixth to the third nucleus, though the third nerve remained intact with no degenerated fibres in it.—The PRESIDENT, Dr BYROM BRAMWELL Dr EDWIN BRAMWELL and Dr D CHALMERS WATSON took part in the discussion.

Dr. HARRY RAINY and Mr H. J STILES gave a lantern demonstration of skiagrams illustrating various Bone Affections in Children.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY—A meeting of this society was held on Jan. 28th, Mr W Bowen Davies (Llandrindod Wells) being in the chair—Dr C W Buckley (Buxton) read a paper on Local Factors influencing Climate with special reference to Subsoil. He said that the chief influence of soil and subsoil was on absolute humidity since different soils had different ratios of absorption and retention of water and thus the amount of water which was evaporated from the soil and which went to increase the amount of aqueous vapour in the air varied with the degree of permeability and the nature of surface drainage. Absolute humidity was a more trustworthy index than relative humidity and had an influence on diathermancy Drainage made a soil warmer as well as drier The different formations were dealt with in detail and their peculiarities as to soil and surface were discussed, and it was shown that the impermeable rocks where the surface drainage was good were the driest and that the clays were the wettest The dryness of porous soils depended on the presence or absence of clay and the surface formation Altitude slightly influenced the humidity and also the daily range of temperature and the rainfall The rainfall was greatly subject to local influences, but on well-drained soils a heavy rainfall was an advantage, purifying the air while it did not increase the humidity The chief contentions put forward were (1) that absolute humidity was one of the most important factors in climate and depended chiefly on local conditions, (2) that geological formation had a great influence on humidity (*a*) by the subsoil and (*b*) by the nature of the surface, (3) that the driest soils were the impermeable rocks and the next the porous soils so far as they were free from clay, (4) that the driest formation was the carboniferous limestone (5) that the amount of rainfall was more influenced by the relation of surrounding hills than by altitude *per se*, and (6) that altitude increased rainfall but tended to decrease humidity—Dr C Theodore Williams (London) congratulated Dr Buckley on striking out a new line in climatology or at any rate of drawing more attention to one of its factors. There was no doubt that on the subsoil and the vegetation depended the amount of rainfall retained in a district. But the amount of humidity, absolute or relative, depended on a good many other causes Nearness to the sea, and especially to coasts exposed to south-westerly winds, the influence of the Gulf Stream, the presence of lofty ranges on which the winds laden with aqueous vapour could impinge and thus condense their moisture, all largely influenced the amount of atmospheric humidity Localities situated to the lee of mountains often had a small rainfall and low humidity percentage, whatever their soil. The relation of soil to humidity in England was so large a subject that it ought to be treated by districts and not generally—Dr S D Clippingdale (London) expressed general concurrence with the statements made by Dr Buckley, but pointed out that the elevation and slope of a surface were probably more important than the nature of the soil or subsoil.—Dr W J Tyson (Folkestone) referred to the difficulty of discussing the paper, as the facts quoted were for the most part indisputable The subject laid the foundation for a further inquiry—viz, what were the diseases and symptoms affected by this inquiry? They knew that certain diseases such as ague had been practically banished from this country by suitable drainage, but there were many conditions of the body acted on by the various amount of humidity in the air that had not yet been noted—Mr G H Thompson (Buxton) said that Dr Buckley's paper had covered the subject as far as possible in the time. There was one point—viz, the rainfall in the Cumberland and Peak districts—which he mentioned as seeming to contradict the law of altitudes, this he (Mr Thompson) thought was easily explained by their nearness to the shores washed by the Atlantic. Another point in noting the larger rainfall in these districts was the configuration which so largely increased the area and was compensatory as well as an important factor in estimating the relative humidity The water holding capacity of different strata was well illustrated in Buxton, being much greater on the millstone grit than on the limestone.—Dr R. Fortescue Fox (London) remarked that whilst the meteorological authorities confessed themselves unable to explain the anomalies of humidity Dr Buckley endeavoured to connect it primarily with the subsoil. This new thesis would require careful examination The *rationale* of the influence of soil on humidity was not sufficiently clear Dr Buckley had not referred to soil temperatures which no doubt affected humidity Whilst sandy soil near the surface was warmer than the overlying air, chalk was of about the same temperature and a clay soil was from one to two degrees colder The capacity for absorption of water of the different subsoils did not appear to be proportional to the humidity With reference to differences of soil, plants and many human beings were undoubtedly far more sensitive than any instruments hitherto devised—Dr Leonard Ll. B Williams (London) thought that though purely local conditions, such as subsoil, might have some influence in determining the amount of humidity, yet there were some general considerations which could not be overlooked. High relative humidity was often regarded as essentially a bad feature in climate—a proposition which should not be received as altogether true High humidity was very useful in some lung conditions and some kidney diseases.—Dr Buckley, in reply, stated that the great extent of the subject prevented him from dealing with every aspect of it and he had therefore only attempted to deal with humidity and with rainfall so far as it was in relation with humidity

HARVEIAN SOCIETY OF LONDON—A meeting of this society was held on Feb 5th, Dr W Winslow Hall the President, being in the chair—Mr Noble Smith read a paper on the Treatment of Congenital Dislocation of the Hip, with especial reference to Lorenz's method of bloodless reduction illustrating the procedure on a child suffering from the disease The adductors of the thigh he said, were first put on the stretch and manipulated by chopping with the edge of the hand and rubbing After a time the muscles gave way Then the posterior muscles were dealt with until the foot could be brought up to the side of the head. The anterior muscles were next stretched by bending the thigh backwards with the knee bent the patient lying on the opposite side of the body With the patient once more on the back and the knee bent the head of the femur was gradually worked down into the acetabulum. In many cases the head of the bone could be heard slipping into the socket. The front of the capsule was then stretched by working the thigh outwards with the knee bent until with full abduction the hollow in the front of the thigh was filled up and the head of the bone could not escape. The limbs were finally fixed in a position of abduction by means of plaster-of Paris.

causes different from typhoid fever He analysed the cause of death in 50 cases, 48 per cent of the patients died from perforation, 20 per cent. from pneumonia, 8 per cent from asthenia, and 6 per cent. from heart complications including pulmonary thrombosis, heart thrombus, and fatty heart In 10 per cent. lung troubles other than pneumonia caused death, hæmorrhage in 6 per cent., and erysipelas in 2 per cent. Dr Hunter said that the mortality was greater formerly, probably in consequence of insanitary conditions These would account for the greater severity of epidemics in some German towns.

Dr A **Elliot** considered that from the military point of view the most important sequela of the epidemic in South Africa was disability, physical and mental In slighter cases men were able to do light work at the base, but for a long time the hardships of trek were quite beyond their powers In commissioned ranks the greatest stress was on the nervous system, producing slowness of cerebration and lack of decision, often rendering the patient unfit for responsible duty in the field Of specific sequelæ the most common and perhaps the most important was phlebitis, variously estimated as occurring in from 5 6 to 25 per cent. of the cases. In epidemics in England and America the frequency was estimated at from 1 9 to 3 8 per cent. As regards the cause of the trouble, the late Dr J W Washbourn suggested that it was due to tinned food and want of fresh vegetables But these led rather to scurvy and deficient coagulation of blood Another suggestion was the wear and tear of marching But an equal proportion of cases occurred in the cavalry and artillery Dr A E Wright found that the coagulability of the blood was increased during convalescence from typhoid fever This he thought, was due to an excess of lime salts from the exclusively milk diet But in South Africa there was a notable lack of fresh milk Probably all that could be said was that this sequela was due to bacterial invasion of the vein walls under conditions of lowered resistance. Embolism, although comparatively frequent in thrombosis associated with influenza and gout, was markedly absent in the thrombosis following typhoid fever Bradycardia occurred in one case, but it might possibly have been due to an excess of digitalis Tachycardia was a much more frequent and persistent trouble As regards the alimentary system, hepatitis with enlargement of the liver without suppuration occurred in one case There was jaundice in one case associated with fatal pneumonia Suppurative appendicitis closely followed enteric fever in one case Probably it was due to an enteric ulcer in the appendix. Two cases of enteric fever immediately followed appendicitis There was late perforation in one patient who had been on ordinary diet for a fortnight. A recent ulcer in the ileum was found to have given way Two cases of parotitis occurred during convalescence, in both there was suppuration As regards dysentery, out of 13 cases occurring during the disease or convalescence six proved fatal, while six patients who had dysentery before enteric fever all recovered. There were nine cases of joint affection, including six cases of arthralgia, two cases of arthritis with effusion, and one case of purulent effusion

Mr G A **Garry Simpson** did not consider it safe to say that a patient was convalescent till the temperature had been normal for three weeks as the bacillus might still be found in the stools and the urine.

Dr J E **Squire** had no hesitation in saying that enteric fever seen by him at Suakin was identical with that seen in England Climatic and other conditions might modify the course and symptoms of the disease, but these modifications were not in essential points In many cases in Suakin the febrile condition continued for two or three months but was probably due to malarial complications He regarded thrombosis as a comparatively frequent sequela. Pneumonia was more often a complication and hæmorrhage and perforation were also rathe accidents occurring during the disease. Joint affections occurred after several cases in the Soudan, chiefly those resembling malarial fever with enteric symptoms, rather than true enteric fever

Dr W **Aldren Turner** called attention to certain sequelæ affecting the central nervous system, such as hemiplegia and myelitis which were clearly due to arterial changes comparable with those occurring in syphilis

Dr E A **Saunders** said that it was of great importance to separate the sequelæ due to the bacillus typhosus from those due to other micro-organisms The case of hepatitis referred to by Dr Elliot was probably also a true typhoid fever infection Other sequelæ might be due to staphylococci and streptococci or to the bacillus coli. Such post-typhoid affections were abscesses—e g, in the larynx—parotitis, boils, bedsores, and the like. It seemed probable that many of the symptoms of severe cases of typhoid fever were attributable to simultaneous affection with the bacillus coli communis.

Dr A. **Whitfield** drew attention to the frequency of severe and persistent furunculosis after enteric fever

EDINBURGH MEDICO CHIRURGICAL SOCIETY

Exhibition of Cases and Specimens—Paralysis of the Deviation of the Eyes

A MEETING of this society was held on Feb 4th, Sir T R **Fraser**, the President, being in the chair

Dr **George A Gibson** exhibited a lad who was suffering from the results of Adhesive Mediastinal Pericarditis. This was a very uncommon disease and the history of this case was briefly as follows Six months before admission to hospital the boy began to suffer from breathlessness, with swelling of the legs and the lower part of the body On admission ascites, anasarca, and albuminuria were found to be present. There was no clubbing of the finger nails and examination of the heart proved chiefly negative The pulse, however, showed the typical characters of the pulsus paradoxus With every inspiration there was a great lessening in the volume of the pulse. The liver was enlarged, reaching to the level of the umbilicus, as well as the spleen, the lower border of which reached below the costal margin. A considerable amount of cyanosis was present and the proportion of hæmoglobin varied from 93 to 105 per cent. Under treatment the ascites, anasarca, and albuminuria disappeared though the liver and spleen still remained large. The case was evidently one of adhesive mediastinal pericarditis, though the diagnosis was not above suspicion and one cardinal symptom insisted on by some writers was absent—namely, the inspiratory collapse of the veins in the neck

Dr G H **Melville Dunlop** demonstrated two cases of Syphilitic Arthritis in children.

Dr **John Thomson** showed a female, aged six years, with a Peculiar Form of Giant Growth She weighed 66½ pounds, or almost double what her normal weight ought to be. The overgrowth affected the whole skeleton No paralyses were present, though the child walked very unsteadily and slowly All movements were awkward and slow She complained of no pain. Her mental condition was below the average. The onset of the disease was indefinite The child was even at birth large and had always eaten more than other children of her age. Her mother had first noticed the great increase in size about 18 months ago

Mr J M. **Cotterill** exhibited several pathological specimens

Dr **Alexander Bruce** read a paper on a case of Double Paralysis of the Lateral Conjugate Deviation of the Eyes The patient was a female, aged 27, who fell from the first step of an ordinary step ladder and struck her head against the leg of a table She was rendered unconscious by the blow and remained so for 20 minutes Next day she suffered from giddiness which became persistent and often caused her to stumble and generally towards the right side. There was also a feeling of stiffness in moving the eyes to the left side as also in moving the left side of the face At this time Mr J V Paterson examined her eyes and found that there was a crossed diplopia present, in his opinion probably due to paresis of the left internal rectus muscle, there was then no other affection of the ocular muscles On examination the left palpebral fissure was seen to be a little more open than the right, due to paresis of the facial muscles on the left side This amounted to an almost complete left-sided facial paresis When she was asked to look towards the right the right eye almost reached the outer canthus, but with a series of nystagmic movements While the left eye began this movement along with the right eyeball it was soon given up after a series of jerks and the left eye took up a position only slightly to the right of the middle line There was, in brief, divergent strabismus when the patient looked to the right all the other movements of the eyes being conserved On looking to the left both eyes would

Reviews and Notices of Books.

The Imperial Yeomanry Hospitals in South Africa, 1900–1902 Edited by the Countess HOWE Three vols London Arthur L Humphreys. 1902. Pp (three vols) 734

THIS is a very elaborate and voluminous record in three handsome quarto volumes of the work which has been done in South Africa in connexion with the Imperial Yeomanry Hospitals Fund That a history of the movement which led to the inception and organisation of these hospitals and an account of the services which they rendered in the late war deserved to be placed on record goes without saying, but whether it was necessary for this purpose to incur all the expense which must have been entailed by the production of this very elaborate, profusely illustrated, and costly work is another matter It is always a thankless and ungracious task to appear to cavil at anything in speaking of good work which has been undertaken in a philanthropic and charitable spirit and carried out on the whole in a highly commendable way We trust, therefore, that if we criticise our criticism will be taken in the same friendly manner in which it is offered.

The time is coming, if it has not already come, when great and radical changes will inevitably take place in our military system. The so-called irregular forces will be more closely amalgamated with the regulars in any forthcoming scheme for organising the Imperial army of the future and philanthropic efforts and provisions that are made in view of aiding the sick and wounded in war, large as these already are, will probably have to be on a still larger and more extensive scale. It is therefore a matter for serious consideration to fix the limits and to determine the nature and quality of the provisions that should be made in these respects if we are to render really useful and efficient aid and if our aim is to be to secure in time of war the greatest good of the greatest number That it will be impracticable to keep pace on such occasions with the growing demands of a luxurious age must, we think, be obvious, nor does it seem necessary or desirable to do so in the interest of those more directly concerned. That in any case everything required for the treatment of the sick and wounded as well as all that can add to their ease and comfort should be freely forthcoming and made available no one can doubt. Too much cannot be done for them in these respects in such circumstances. But it must occasionally happen that in the competitive trials of charitable societies and communities with one another, as in the case of the hospitalities of society, an effort is made to outdo the rest. The risk is lest, losing sight of the primary and fundamental object, such efforts may err on the side of ostentation and extravagance.

Let us turn, however, from such general reflections as these to the consideration of the volumes under review The intrinsic value of the information contained in them—in the way of additions to medical science or of guidance in designing and organising future war hospitals and as to the nature and amount of the equipment and medical and technical materials to be provided—is not, and possibly was not designed to be, in proportion to what might be expected from their size and handsome style and "get up." The total funds—£145,000 realised by collections, Government subsidies, and other sources of income, with the sale of materials and so forth—altogether amounted to over £174 000. There was consequently no lack of money available nor was there any parsimony about the way in which these hospitals were supplied, for if all we have heard about them be true they were very fine hospitals and were furnished on a scale and with an elaboration of detail and comfort which left nothing to be desired and which probably never took place in war before. It is only right to say that the work in connexion with the inauguration of these hospitals was the work of ladies. When the great call was made upon the patriotism of the country a strong committee was formed, Her Majesty Queen Alexandra (then Princess of Wales) being president and Countess Howe, who edits the volumes under review, occupying the chair. Earl Howe acted as honorary secretary All connected with the movement, whether at home or at the seat of war, appear to have laboured together with unselfish zeal and enthusiasm in the cause and to have put forth every effort to make the organisation and conduct of the Imperial Yeomanry hospitals a great success.

In addition to the large base hospital at Deelfontein other hospitals at Pretoria and elsewhere were opened as well as several subsidiary establishments The undertaking was therefore organised and conducted, as the military operations extended, on a big scale. The special reports deal with each hospital or section separately but it would be impossible within any reasonable limits of space to refer to all of them. That of Lieutenant-Colonel A. T Sloggett, C M.G , R.A.M C is an interesting and instructive one It treats exhaustively of the base hospital at Deelfontein which was erected in the short period of a fortnight under rather more than the usual difficulties experienced by the medical authorities during the war It may be noted that the Aldershot system of conservancy was carried out here with complete success. The medical report of this hospital is by the late Dr J W Washbourn, C.M.G There were in all 4731 medical cases with 262 of enteric fever, among 211 of which it was definitely recorded that 186 were *uninoculated* and 25 *inoculated*, with respectively 20 and four deaths, making a percentage of 16 for inoculated and 10 for uninoculated cases. It was also noted that inoculation had no marked influence in preventing or modifying the disease. The type of the fever in South Africa was much the same as in England or America. The surgical cases were 1157, with only 185 cases, however, of bullet wounds, owing probably to its being a base hospital. There were two useful innovations in the shape of departments for ophthalmic and dental work.

In the x ray department it was found that neither batteries nor accumulators were of any practical use, the good radiographs in the report were obtained by means of a dynamo run by an oil engine. No. 3 Model School Hospital at Pretoria was really a portion of the field hospital. There were in this hospital 3732 medical cases, the remainder (1324) being surgical with 235 gunshot wounds Enteric fever and dysentery were the chief diseases and these were most prevalent during December and January, showing a rise during March. There were 692 cases of the former (enteric fever), with 55 deaths, and 475 cases of dysentery with 15 deaths accounting together for about 75 per cent. of the whole death rate of the hospital.

The work of the bearer company and field hospital is lucidly and well described in the report by Mr C Stonham C M.G After some vicissitudes at sea, including a collision with the s.s. *Mexican* which sank, the bearer company intrained at Cape Town and went to Bloemfontein and afterwards "trekked" all over the Orange Colony and both the Eastern and Western Transvaal. There are 342 cases of gunshot wounds reported among the 1267 cases admitted into this field hospital with a very few shell wounds. The total number of admissions into the various hospitals were 13,327, being 9814 medical and 3513 surgical cases. Among the latter many interesting and instructive cases of gunshot wounds occurred and are described. The axiom ' in abdominal small bore bullet wounds do not operate' has become a practical rule in military surgery and we do not find any record of laparotomy for gunshot

Lorenz had shown that this position must be retained for six months. The thighs were then brought down half way and put in plaster again and were gradually straightened at the end of two years As to the suitable age for reduction, for double dislocation the best results were obtained up to six years of age. For a single dislocation the time might be extended to nine years of age. Older patients must be prepared by preliminary stretching and exercise Lorenz had cured a patient aged 28 years Mr Noble Smith thought that the advantages of the bloodless method were that it was a perfectly safe procedure, even such accidents as a fracture of the femur leading to no ill effects, that there was no risk of a stiff joint, with consequent crippling for life, that young children were not affected by being kept off the feet for two years, and as a matter of fact patients were not kept lying down the whole time, but pushed themselves about on a stool, which was shown. A block was also shown which was very useful for placing under the thigh during manipulation —Mr T H. Openshaw had used methods of manipulation for seven years and in 30 cases had had good results in about a third of that number Lorenz's method had been gradually improved, especially in the retention of the fully abducted position for six months In this time probably the glutei and other muscles became shorter and prevented re-dislocation. Possibly the head of the femur might ultimately make its way through the capsule into the joint, but often the bone could not be got into the acetabulum. In the open operation, if the cartilage was not interfered with there was no ankylosis.—Mr J Jackson Clarke quoted a post-mortem examination on a child dying from diphtheria one month after Lorenz's operation to show that the head of the femur could be replaced in the acetabulum. The glenoid ligament was sometimes so thick as to make replacement very difficult. He called attention to friction bands underneath the plaster splints whereby the skin could be kept in good order Difficulties in the treatment were due to parental neglect and indifference to this kind of work In cases difficult of reduction, much ecchymosis might be caused. In such cases it was better to do a preliminary operation of stretching or dividing muscles —Mr P L Daniel said that much improvement had taken place in Lorenz's methods and he instanced the thoroughness of the work of applying plaster of Paris splints He thought that cases treated by Lorenz's methods contrasted most favourably with the results of the open operation —Mr Peyton T B Beale wished to know what happened to the ligamentum teres after reduction Did it shrink or did a new ligament form ?—The President said that the subject was of importance to the general practitioner, with whom the fact that Lorenz's method did not endanger life or limb would have great weight.—Mr Noble Smith, in reply, said that the condition of the ligamentum teres had not been verified.—Mr P Sidney Spokes read a paper on the Immediate Regulation of Misplaced Teeth.

Cardiff Medical Society —The ordinary monthly meeting of this society was held on Feb 5th, Dr R. Prichard, the President, being in the chair —Professor A F Dixon exhibited the new Projection Lantern used in the anatomical department of University College, Cardiff (by Dr John Gordon of Glasgow), and demonstrated its method of working He then showed in the lantern photographs by Dr T H. Bryce and Dr J H Teacher of Glasgow illustrating the maturation, fertilisation, and segmentation of the ovum of echinus esculentus, from the preparations of Dr Bryce —Mr William Sheen gave a lantern slide demonstration of Fractures of the Lower End of the Humerus in Children. He first showed a series of x ray photographs of normal elbow joints in children between the ages of one and a half and 16 years He demonstrated from these the situation of the different epiphyses, their size and shape and the times at which they appeared, and called attention to the importance of not mistaking a normal epiphysis not yet joined on, for a fracture. He then by means of a diagram indicated the common types of fracture and showed that they usually involved the diaphysis, pure epiphyseal separations being extremely rare A series of x ray photographs of cases recently under his care was then shown to demonstrate fracture of the external condyle and transverse fracture above the condyles. The importance of taking photographs of both the injured and normal elbow and also of taking a lateral as well as an antero posterior view was also alluded to The symptoms and course of such cases, the possible complications, particularly deformities and nerve injuries, and the line of treatment to be adopted were briefly described.—The President, Dr P Rhys Griffiths, Mr W B C Treasure, and Professor Dixon commented on the demonstration and Mr Sheen replied.—Professor Dixon exhibited on behalf of Dr W S Haughton of Dublin and himself a series of stereoscopic radiographs illustrating the Structure of each of the Bones of the Skeleton The pictures showed in a striking manner the arrangement of the lamellæ in the shafts of the long bones and in the cancellous tissue A distinct spiral arrangement of the lamellæ could be made out in all the long bones in man and was especially marked in bones like the humerus and femur The lamellæ in question formed right- and left-handed spirals which intersected one another They could be seen to undergo a change in direction near the articular surfaces in such a manner as to bring the ends of the lamellæ into planes perpendicular to the surfaces of pressure. Although perhaps best marked in the bones mentioned the spiral lamellæ were also to be seen in all bones with a tubular formation and in each case they were very well developed in positions of curvature where they undoubtedly gave greater rigidity to the skeleton. Their arrangement was easily demonstrated in the ribs and also in structures like the transverse processes of the vertebræ

Edinburgh Royal Medical Society —A meeting of this society was held on Feb 6th, Dr S A. K. Wilson being in the chair —Dr Shaw read notes on a case of Hemiplegia in a girl, 15 years of age There was hemianopsia but no optic neuritis. There was very slight sensory disturbance The diagnosis was that the case was one of cerebral tumour affecting the posterior part of the internal capsule and the optic thalamus —Dr S Gilford read notes on a case of Extensive Cancer of the Rectum with Stricture of the Rectum. The patient had also severe aortic incompetence. Inguinal colotomy was performed, the operation being carried out under eucaine. During the operation it was observed that the handling of the parietal peritoneum caused pain and a change in the pulse, but that no such changes took place in regard to the visceral peritoneum.—Dr A. Murray Wood read a dissertation on the Rheumatic State in Childhood. He began by pointing out the easy diagnosis of rheumatism in the adult and the difficulty encountered in diagnosing the condition in children. After discussing the influence of sex and heredity on rheumatism in childhood he went on to enumerate the various symptoms and complications that might be met with, and he showed how far these assisted in diagnosing and in giving a prognosis of the case. He said that the presence of the subcutaneous tendinous nodules was the only sure diagnostic sign in children.

Rochdale and District Medical Society —A meeting of this society was held on Feb 5th, Mr W Stanwell, the President, being in the chair —Dr W Hirst Bateman read Notes on Two Cases of Extra uterine Pregnancy The first case occurred in a recently married woman and was treated at a very early stage of the pregnancy by operation on account of severe pain. Abdominal section was performed and the sac was found to be protruding from the fimbriated extremity of the Fallopian tube. The patient made an uninterrupted recovery In the second case the patient had been married four years and there had been no previous pregnancy Rupture of the sac apparently occurred in the second month, but the symptoms were not so urgent as to necessitate immediate operation and expectant treatment was adopted The patient was kept at rest in bed and gradually improved. Four months later she was practically well. Dr Bateman urged that operation was not always necessary in early cases —The President Mr H. H L Hitchon and Dr W J Kerr believed that it was better to operate before symptoms became urgent.

University of Cambridge —The new demonstrators of anatomy are Dr T Manners Smith (Downing) and Dr H. W Marett Tims (King's) The delegates of the University to the Brussels International Congress of Hygiene to be held next September are Dr D MacAlister, Professor G Sims Woodhead and Mr Nuttall Professor A. Macalister has been appointed an elector to the chairs of surgery and medicine (Downing), Dr D MacAlister an elector to the chair of zoology, Professor T C Allbutt an elector to the chair of anatomy, Professor Woodhead an elector to the chair of physiology, and Dr W H. Gaskell an elector to the chair of pathology many cases from the employment of children in the streets for the purpose of earning money for their parents, the facts are clearly proved by the reports of committees appointed by the municipalities and by police statistics. In 1882 the Manchester corporation obtained an Act enabling it to deal with street-trading children, providing that no child under the age of 14 years should, unless he had obtained a certain standard of education, be employed as a street-trader after 9 P.M. in the summer and 7 P.M. in the winter. The regulations made were to the effect that all children between the age of 12 and 16 years should be entitled to a licence provided that they intended to trade in the streets of the city, that they were not unfit to trade through being sickly, blind, deaf, dumb, deformed, or mentally deficient, and that they had the consent of their parents to their being licensed. The plan has worked well and the condition of the juvenile street-traders has improved.

Dr. Francis Warner read a paper at the congress on the Physical Training of Children from the point of view of exercises adapted to produce an educative effect. Progressive free-hand exercises made by the pupil in imitation of the teacher's finger movements in combinations, one at a time, two at a time, were illustrated, the author explaining the educative effects that may thus be obtained without the use of words in dull and backward children. "Exercises in transfer movements" were thus explained. 'Let a child hold out both hands, take his left hand in yours and explain to him that he is to move the fingers of his right hand in the same way as you move those in his left. Let him shut his eyes, then the action in his right hand will be an imitation of your passive movements of his left hand. Here the feeling of movement in the left hand controls and directs the action.' In view of the expected report of the Royal Commission appointed to inquire as to the various methods of physical training, the precautions to be taken in its general introduction, and the adaptations of method required for certain groups of children, it is advisable that all forms of training should be considered. It was resolved at the congress—

> That having regard to the important relation of physical exercises to intellectual as well as to muscular development they should form an integral part of education and that teachers should be specially prepared for teaching them by instruction in our training colleges.

This report is unusually interesting and readable, the various subjects touched on have been ably dealt with and throw much light upon the lines of action which it is desirable to follow for the benefit of children.

The Student's Guide to Medical Diagnosis. By SAMUEL FENWICK, M.D. St. And. and Durh., F.R.C.P. Lond., late Consulting Physician to the London Hospital; and W. SOLTAU FENWICK, M.D., B.S., M.R.C.P. Lond., Senior Physician to the London Temperance Hospital, Physician to the Evelina Hospital for Sick Children. Ninth edition. London: J. and A. Churchill. 1903. Pp. 480. Price 9s.

THAT Fenwick's Medical Diagnosis is a well known and highly popular book there is no need to tell. The first edition was published by the late Dr. Samuel Fenwick towards the end of 1869 and arose out of a desire to assist students attending the medical out-patient department of the London Hospital. It was at the time original in design and admirable in construction and execution and its merits as a simple and lucid guide to medical diagnosis were speedily recognised. Since the date of the appearance of the first edition it need scarcely be said that medical science has not stood still but has been progressing with rapid strides, and a conscientious attempt to keep abreast with this progress may be traced in the numerous editions which have been called for from time to time. The present is the ninth edition and the fact speaks for itself. It is curious as well as interesting to follow the gradual growth and to notice the progressive changes that have been rendered necessary and to contrast the latest with the earlier editions, while recognising that the aim has been, as far as is practicable, to preserve a continuity of method and plan throughout. The present edition makes an excellent and very useful little book for students and practitioners. What is stated in its brief preface is fully borne out by our examination of it—namely, that the work has been entirely revised and that several new illustrations have been added to it.

Outlines of Psychology. By WILHELM WUNDT. Translated by CHARLES HUBBARD JUDD, Ph.D., Instructor of Psychology, Yale University. London: Williams and Norgate. 1902. Pp. xxii., 390. Price 8s. net.

PROFESSOR WUNDT'S "Outlines" does not constitute an introductory work to psychology but is, in its present form, a somewhat advanced and systematic work in which the standard of exposition is throughout high and even elaborate. A considerable knowledge of psychological and scientific terminology is needed for the due understanding and appreciation of this work. The author recognises at the outset two chief forms of psychology—the metaphysical and the empirical—and in an elaborate tabular summary he gives the various subdivisions of these. The exposition of the subject begins after his preliminary survey with an elaborate analysis of "psychical elements"—i.e., simple sensations and simple feelings. A 'general sense' concerned with the appreciation of conditions of space and time is regarded as "belonging to *all* beings endowed with mind," and this 'general sense" is further held to be capable of analysis into sensations of pressure, heat and cold, and pain. The discussion here is highly abstract and difficult to follow unless the closest attention is given to it. Passing next to the subject of compound sensations and feelings it is shown that all such sensations and feelings contain more than the qualities of their constituent elements—in other words, that new attributes peculiar to the compounds always arise as a result of the combination of elementary sensations and feelings. Ascending thus in the scale of psychological complexity an exposition is given of the nature of our ideas of space and of time, of emotions, and of volitional process. The succeeding portion of the work deals with the interconnexion of complex mental processes such as are commonly included under the terms 'consciousness,' 'attention,' "association of ideas," and 'apperception processes," the last term being used by Professor Wundt to include a variety of psychical processes of which but little is as yet known. This section of the work concludes with a brief account of the psychological aspects of dreams, sleep and hypnosis.

The next section touches briefly upon the psychical attributes of animals, the mental development of the child, the development of speech, of customs, and of myths and the subject of the collective will and social consciousness. The work concludes with an account of the metaphysical concept of mind and of the principle of causality.

In estimating a work of this kind comparisons are hard to avoid. The classical "Principles of Psychology" of Herbert Spencer and the works of James and of modern authors show the inevitable influence of the principle of evolution, while the standpoint taken by modern psychological investigation is mainly biological. Professor Wundt's work, while containing many bibliographical references to investigations of this sort is permeated throughout with the metaphysical and speculative spirit. Its tendency is to be deductive rather than inductive, to be abstract rather than practical, and it is thus less likely to suit medical readers whose requirements lie more in the direction of the inductive and the biological sciences than in metaphysical speculation. The work is a remarkable and excellent type of the older psychology slightly influenced by the new spirit.

wounds in the report. We may incidentally refer to a valuable paper on the use of Sulphur in Dysentery by Dr G E Richmond. This has already appeared in THE LANCET [1]

The work is abundantly illustrated with reproductions of photographs and skiagrams, all of which are excellent. The former will bring back vivid memories to readers who have been through those or similar scenes, while others who have not will be enabled to realise something of what their *confreres* have seen and done during their war service in South Africa.

A Practical Handbook of Midwifery By FRANCIS W NICOL HAULTAIN, M D, F R.C P Edin Second edition, entirely revised. Illustrated London The Scientific Press, Limited 1903. Pp 253 Price 6*s* net.

AFTER a lapse of some ten years Dr Haultain has published a revised edition of this book which appeared first in 1893 It is intended as a practical help to the busy practitioner and as a reminder to the student of the points of practical importance in the study of obstetrics It consists of a short *résumé* of the chief facts of midwifery put clearly and very succinctly, most of the information being in the form of tables Such a work must of necessity suffer from its very briefness It is impossible for the author in the limited space allotted to the various subjects to discuss the reasons for the recommendations which he makes, and as a natural consequence not infrequently statements are met with to which other teachers might well take exception The information is, however, upon the whole good and accurate and the book forms, as is claimed for it a very practical handbook of midwifery It is of importance as giving what may be taken to represent the teaching of the Edinburgh School in great part, and it is interesting to ascertain the author's opinions upon various disputed points In the treatment of eclampsia we find the administration of pilocarpine advocated, a drug the use of which in this disease, at any rate, is almost universally condemned by London obstetricians As might be predicted, Dr Haultain prefers the use of axis traction forceps in the treatment of cases of delivery complicated by the presence of a flattened pelvis. Indeed, he uses axis-traction forceps in all cases of delivery by forceps and here we entirely agree with him. In considering the treatment of cases of accidental hæmorrhage we notice that he says, "Plugging the vagina has been recommended in cases of external hæmorrhage with an *actively contracting* uterus" The teachers of the Dublin School, who are the chief exponents of the treatment of external accidental hæmorrhage by plugging the vagina, recommend it in cases where the uterine pains are absent or feeble, a condition just the opposite of that quoted by the author Possibly he is not alluding to the Dublin method A departure from the ordinary teaching is that given by Dr Haultain in his description of the management of breech presentations In cases where the head is extended and delayed at the brim of the pelvis he recommends the Prague method of delivery, while in cases where the head is extended and delayed in the cavity of the pelvis he prefers the application of the fingers to the face and to the occiput of the child Our own experience does not bear out the statement that decapitation is best performed with a pair of long, straight, blunt-ended scissors In a really difficult case the instrument least dangerous to the mother and most efficacious is the saw edged decapitating hook It is surprising to find on p 42 in the discussion of the treatment of cases of cancer of the cervix complicating early pregnancy the induction of abortion recommended. We thought the almost universal practice at the present day was the performance of vaginal hysterectomy whenever possible in such cases, a mode of treatment of which nothing is said.

Although, as we have pointed out, there are here and there statements in the book upon which differences of opinion may well exist, yet upon the whole it should prove of value to the practitioner and the student.

Report of the Third International Congress for the Welfare and Protection of Children, London, 1902 Edited by SIR WILLIAM CHANCE, Bart. London P S. King and Co Pp 348. Price 2*s* 6*d*

THIS volume will prove attractive to those who wish to review the work which is being carried on in various directions for the benefit of childhood in this and in other countries. It expresses the experience and opinions of many acknowledged authorities on questions of health, legislation, and education as they bear on different classes of children Dr J F J Sykes, medical officer of health of St. Pancras, contributes an article on Hygiene and Sanitation in the Home and at School and points out the fact that diphtheria has enormously increased since the introduction of the Education Act, probably largely due to the aggregation of children Doubtless infectious diseases mostly spread in schools where points of contact are numerous. This fact is becoming more and more realised. The lower age-limit for school attendance was discussed and reference was made to Dr A. Newsholme's statistics which show that 11 per cent. of the children on school registers are under five years of age, 22 per cent. are between five and seven years of age, and 67 per cent. are between seven and 15 years of age. There seems to be a growing consensus of medical opinion that seven years should be the age fixed below which no child should be allowed to attend a public elementary school, a resolution to that effect was carried in the medical section but negatived by the congress. It was pointed out by Dr Sykes that overcrowding in homes is the great enemy of family life, while well constructed sanitary tenements may be the best remedy for those who must live in the towns they are not without attendant evils, and the extension of cheap means of communication with the suburbs must be looked upon as affording the best prospects for a healthy child population A plea was also raised for the extension of school classes in cooking and housewifery

As related to the home and the school we refer to Mr C Loch's paper on State and Parental Control He says "In so far as the sense of the reciprocal nature of the relation between parent and child is lost, improper and excessive use is likely to be made of any provision made by the State for destitute, abandoned and neglected children Parents then seek to turn to their private advantage the earnings and ability of their children whom they have not endeavoured to educate or control, and the child or young person is not retained sufficiently long under special training and guardianship to reap the full and lasting benefit of the education afforded him." The parent is too often anxious to be rid of a child when the child becomes a burden to him and equally anxious to secure the services and help of that child when he is sent forth from the institution. Mr Loch moved at the congress —

> That it is desirable that the laws relating to the control and welfare of children should be considered by a departmental committee or Royal Commission with a view (1) to prevent the influence of unsatisfactory parents on children placed under institutional care undoing the good results of the education given to the children and (2) lessening the temptations to parents to let their children be maintained by public authorities

This resolution was carried.

The paper last noticed is illustrated in a very practical manner by a contribution by Mr Robert Peacock, chief constable of the city of Manchester, on Employment of Children with Special Reference to Street-trading by Children This shows plainly the evils which result in very

New Inventions.

THE NEW FINSEN REYN LAMP

WHEN attending Professor Finsen's Institute in Copenhagen I found the authorities there hard at work experimenting with a new lamp that had been devised by Professor Finsen and one of his colleagues, Dr Reyn, and after a thorough, prolonged, and satisfactory trial, both in the laboratory and the institute, this lamp has now been issued with the guarantee and authority of the Institute. The first of these lamps sent out from Copenhagen has arrived in this country and is shown in the accompanying illustration. The principle on which the lamp is constructed is entirely that of the older and larger Finsen lamp, but one patient only can be treated at a time instead of four as with the latter thus insuring privacy in the treatment of each individual case—a point of considerable importance in England. The lamp consists of three parts—namely, the arc light, the concentration apparatus or telescope, and the compressor, the two latter being connected with a water circulating system for cooling purposes The lamp and telescope are placed at either end of a connecting rod which in turn is mounted on a moveable stand provided with a universal movement mechanism at its upper end. The arc lamp is for a direct current of 55 volts and 20 amperes and the carbons, which are automatically fed, incline at an angle directing the rays on to the concentration apparatus. It is mounted on a pin to which it can be fastened at the necessary height by a screw, and this in turn is attached to a rack-and-pinion arranged on the connecting rod giving a forward and backward movement, so that the lamp may be placed at any required distance from the telescope. LIBRARY TABLE

Three Clinical Lectures on the Diagnosis and Treatment of Rectal Diseases By F C WALLIS, F R C S Eng, Assistant Surgeon to Charing Cross Hospital and to St. Mark's Hospital London The Medical Publishing Company, Limited. 1902. Pp 87—These three lectures were delivered last year at the Medical Graduates' College and Polyclinic and were published in the *Clinical Journal* They contain a very readable account of the more common lesions met with in the rectum and the treatment is described with especial fulness While the book on the whole is representative of the general teaching of the surgery of this region Mr Wallis is not afraid to think for himself and several original ideas are given and well supported by pathological and clinical evidence. Mr Wallis holds that pruritus ani is nearly always due to a small shallow ulcer of the mucous membrane situated between the two sphincters, frequently in the posterior part of the circumference He finds that the healing of this ulcer is followed by a cessation of the irritation. We are in accord with his contention that the common non malignant ulceration of the rectum is generally not syphilitic in origin, as is often taught, but probably septic. The lectures were well worth reprinting

Hazell's Annual, 1903 a Cyclopædic Record of Men and Topics of the Day Revised to Dec. 31st, 1902. Edited by W PALMER, B A. Lond. London Hazell, Watson, and Viney, Limited. Pp 750 Price 3*s* 6*d* net—This valuable work of reference has been published this year about a month later than usual in order to include a complete record of events for 1902, including the Education Act, the Metropolis Water Act, and the new scheme for the entry and training of naval officers issued on Christmas Day All the permanent features of the book have been revised and rewritten and the policy of classifying and grouping cognate articles has been carried still further Reference is made to the bequests of Mr Cecil Rhodes and the public house trust movement, and among other new articles are those on Christian Science, Consumption Sanatoriums, British and Foreign Copyright, London Medical Schools, Motor Vehicles, and the Nobel Foundation. There is also a valuable summary of the debates and legislation of the session of 1902, including a detailed analysis of all the principal Acts passed, all the principal Bills introduced, and the reports of Parliamentary committees and Royal Commissions. In "Hazell's Annual," indeed, is to be found the true meaning of *multum in parvo* and conciseness has been obtained without obscurity

JOURNALS AND MAGAZINES

The Review of Neurology and Psychiatry opens its first number with original articles on Local Panatrophy, by Sir William Gowers, on Psychiatry in General Hospitals, by Sir John Sibbald, and on the Relative Frequency of Disseminated Sclerosis in this country and in America. These are followed by abundant abstracts from foreign reviews and journals, giving an excellent *résumé* of current practical work bearing on neurology and medical psychology The articles and abstracts are both interesting and attractive and cannot fail to give the review a healthy "send off" on what we hope may prove to be a successful career The editor, Dr Alexander Bruce, is himself a well known worker and his name is a guarantee that readers of the new periodical will find their time profitably spent in its perusal The review will be issued monthly, and the bibliography which is a feature of the contents must prove useful for purposes of reference

Cambridge Review—The number of date Jan. 29th is enlivened by the productions of two poets, one of whom, modestly veiling his identity under the initials "F M C," has felt his soul stirred within him by the numerical disproportion between the students of anatomy and the "subjects." He has accordingly unburdened himself in a "Ballad of Cadavers" in six stanzas, humorous enough except for one dismal prophecy which we trust may not be fulfilled —

"When two must share an arm or leg
And four take head and neck,
Some forty three per cent. may pass—
The rest will be a wreck."

Mercy and Truth.—The January number contains an article on Medical Work among Women in Multan, in the Punjab, by Dr Wilhelmina Eger, and an illustrated Description of Progress in Hakodate, Japan, at which place the missionary is Dr W W Colborne

HOSPITAL MAGAZINES

St Bartholomew's Hospital Journal for December, 1902, contains, among other interesting matter, the report of a paper read before the Abernethian Society by Dr W d'Este Emery on the Specific Antibodies. The paper is accompanied by eight illustrations The following story is given SCENE—Out-patient room Physician (unravelling the finer points of the case) "Are you depressed in spirits?" Patient "Yes, sir" Physician "Why is that?" Patient "Well, sir, since I've been out o' work I haven't been able to buy 'em"

St George's Hospital Gazette for January contains a paper describing a Russian hospital on the banks of the Dwina "In the matter of medicine," says the writer, "they are prehistoric" Consequently "it is difficult to decide whether to treat it (the hospital) from a medical point of view or as a subject of antiquarian research." The writer does his best to deal with it from the medical point of view It is difficult to believe that even in this remote corner of the world notes of cases are kept in chalk. The problem of ventilation has been solved in this hospital by having no ventilation at all The paper is thoroughly interesting

London Hospital Gazette for December, under the heading of Random Notes concerning Stimulants, prints a very readable and instructive article from the pen of Dr. A. E Sansom The author concludes by saying "If you want, as you should, to know much about brandy the writer strongly advises you to peruse carefully a report in a recent number of THE LANCET" This is the sort of commendation that is particularly flattering to us, as our investigations of food stuffs and allied subjects are undertaken exactly with the idea of giving medical men information of a practical nature which cannot be found in text-books.

Westminster Hospital Gazette—There is nothing better in the January number of this journal than the following, which has a familiar ring to us —

"OUR DOCTORS

He must not walk his rounds for fear his patients think him poor
For dearly do they love to see a carriage at their door
And if his horse is fat he must have little work to do
And if tis lean the reason is he starves that poor old screw
If he calls upon his patients every day when they are ill,
The reason is he wants to make a great big doctor's bill
If he calls on them less frequently thus lessening their expense,
The chances are he ll be accused of wilful negligence.
About his own afflictions he must never say a word—
The notion of a doctor being ill is too absurd!
And when perhaps from overwork he's laid upon the shelf
His sympathising patients say Physician, heal thyself!"

BRADFORD AND WEST RIDING MEDICO-ETHICAL UNION—The annual dinner of this society took place at the Victoria Hotel, Bradford, on Feb. 5th Nearly 60 members and guests were present. Dr J Dunlop, the retiring President, was in the chair After the chairman had given the toasts of "The King, the Queen, and the Royal Family," Dr W H. Horrocks proposed the toast of "The Bradford and West Riding Medico-Ethical Union." This was responded to by the President (Mr H. Shackleton) and the secretaries, Dr J Metcalfe and Dr W Mitchell. The toast of "The Ladies" was proposed in a humorous speech by Dr A Bronner and responded to by Mr W Handcock. An excellent musical programme was then given by the ladies and members present.

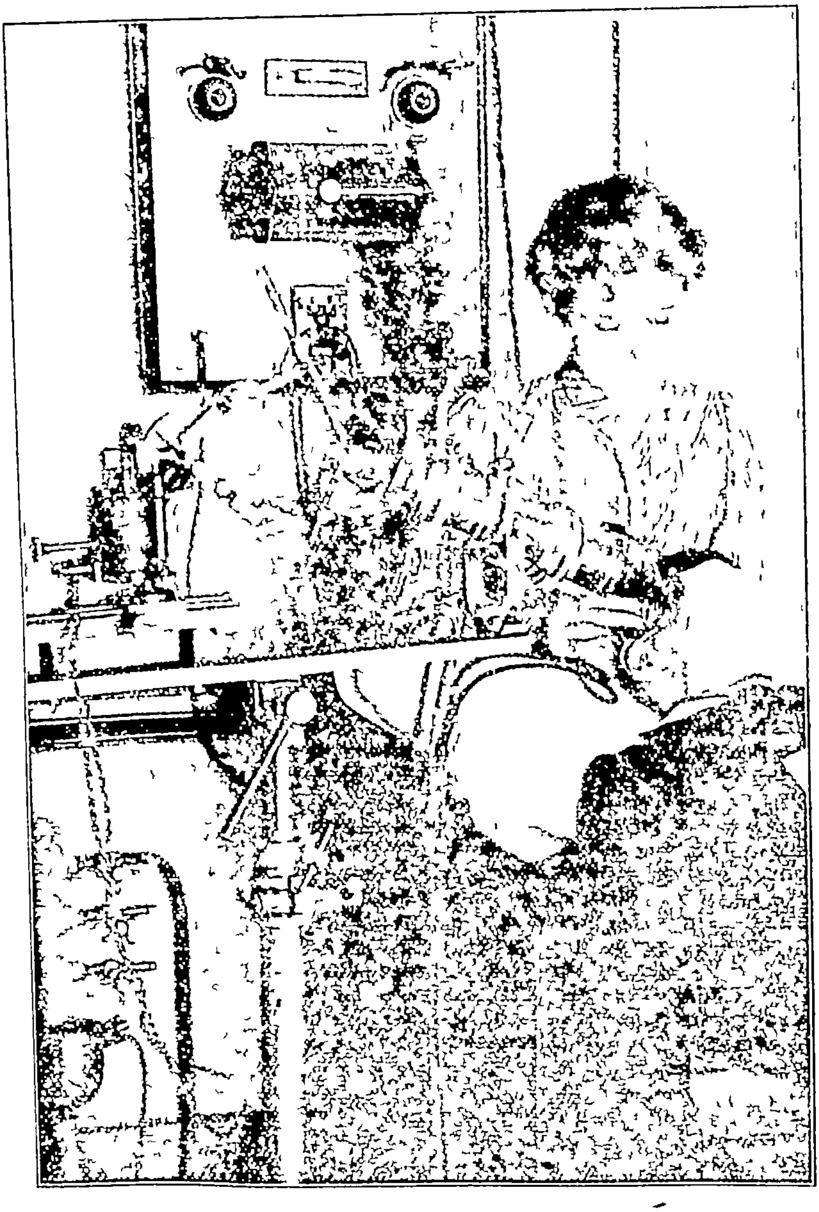
THE NEW FINSEN REYN LAMP

WHEN attending Professor Finsen's Institute in Copenhagen I found the authorities there hard at work experimenting with a new lamp that had been devised by Professor Finsen and one of his colleagues, Dr Reyn, and after a thorough, prolonged, and satisfactory trial, both in the laboratory and the institute, this lamp has now been issued with the guarantee and authority of the Institute The first of these lamps sent out from Copenhagen has arrived in this country and is shown in the accompanying illustration. The principle on which the lamp is constructed is entirely that of the older and larger Finsen lamp, but one patient only can be treated at a time instead of four as with the latter, thus insuring privacy in the treatment of each individual case—a point of considerable importance in England. The lamp consists of three parts—namely, the arc light, the concentration apparatus or telescope, and the compressor, the two latter being connected with a water circulating system for cooling purposes The lamp and telescope are placed at either end of a connecting rod which in turn is mounted on a moveable stand provided with a universal movement mechanism at its upper end. The arc lamp is for a direct current of 55 volts and 20 ampères and the carbons, which are automatically fed, incline at an angle directing the rays on to the concentration apparatus. It is mounted on a pin to which it can be fastened at the necessary height by a screw, and this in turn is attached to a rack-and-pinion arranged on the connecting rod giving a forward and backward movement, so that the lamp may be placed at any required distance from the telescope. The



The Finsen Reyn lamp at work

of supply and demand. Good nurses are not forthcoming at the wages and conditions offered. The Metropolitan Asylums Board was confronted with the same difficulty in its fever hospitals. It solved the difficulty by offering higher wages and better conditions of service and the Local Government Board would be well advised to adopt similar means. In the interests alike of the medical profession, the public, and the Poor law nursing service we feel bound to enter our protest at the earliest moment against a retrograde proposal. A large section of the public is becoming impatient at the non solution of this important question of workhouse nursing The constitution of this departmental committee was unsatisfactory, its recommendations carry but little weight, and the time has come for a Royal Commission to be appointed in order thoroughly to investigate the matter

◆

The Treatment of Intussusception

A TRULY remarkable series of cases of intussusception was recently met with at the London Hospital, where within nine days seven cases of this condition were admitted into the wards They were all under the care of Mr HUGH M RIGBY who contributed a detailed account of them to THE LANCET of Feb 7th (p 364) One of the seven patients was in a moribund condition when admitted and died four hours later, and therefore we need hardly consider that case, but the remaining six patients were submitted to operation and of these five recovered The one fatal case required resection of a portion of the bowel and this complication of the operation for intussusception is universally recognised as of the gravest prognosis Within recent years the whole question of the treatment of intussusception has undergone a great change and an examination of the reasons for the adoption of the present methods should be by no means devoid of interest.

Not long after the pathology of intussusception was investigated the idea of forcing back the invaginated bowel by fluid pressure arose The earlier attempts were made with air which was forced in by means of a syringe, later liquids were employed, water being chiefly used, though olive oil has been advocated Hydrogen and carbonic acid gas have also had their supporters There is a very obvious limitation to the action of both inflation and injection and this is imposed by the ileo cæcal valve. Any intussusception limited to the small bowel cannot be affected by the distension of the large intestine, for distension of the cæcum closes the valve firmly It is true that it has been demonstrated that in excessive distension of the cæcum some of the contents may escape upwards through the valve, but this can only happen to a slight extent and when the distending force is very great. Therefore these methods are possible only in some forms of intussusception. The treatment by inflation, and especially by injection did certainly succeed in reducing some intussusceptions, and this was so, not only in slight cases, but even in extensive cases, as in one recorded by Dr E MANSEL SYMPSON, where several inches of bowel protruded from the anus In what proportion of cases methods of distension succeed cannot definitely be stated, but the statistics collected by Dr F HOLME WIGGIN of New York, which give the percentage of successes as 25, may be considered as not underestimating the beneficial results of the treatment. Distension of the colon too, is not without danger, for numerous cases are on record in which rupture of the bowel has occurred. Mr R LAWFORD KNAGGS has collected seven cases in which this accident was encountered and no wonder need be felt at the rupture of the bowel under the conditions in which distension is usually performed, for in most cases no attempt is made to gauge the pressure exerted by the distending fluid. A syringe is usually employed and the pressure exerted by the hand on the syringe is a very poor index to the pressure in the bowel. A curious fact is here of great importance and that is that the smaller the syringe employed the greater is the distending force The quantity of the liquid injected is an equally fallacious test of the pressure in the bowel, for Mr D'ARCY POWER has shown that the capacity of the colon varies greatly in different children. Indeed, in one of the fatal cases of rupture of the bowel only nine ounces of water had been injected. The process of distension may also be very exhausting to the child, especially if it has to be repeated, as is necessary sometimes when this is the sole method of treatment employed. In some cases the process has been repeated four or five times. An important objection to the treatment by distension is that it is often very difficult for the surgeon to be certain that the reduction is complete, for so small a portion of bowel may remain invaginated that nothing can be felt through the abdominal wall and yet a fatal issue may follow On the other hand, the surgeon may feel a small swelling after distension has been practised and may think that reduction has not been complete, though the mass felt is only œdematous bowel

For these and other reasons there has been of recent years a growing tendency to resort to abdominal section at an early stage of a case of intussusception Even in the past a laparotomy frequently followed unsuccessful attempts at distension, but these unsuccessful attempts had been often so energetic and persistent that the severe exhaustion that had been induced entirely precluded the possibility of a successful result following the abdominal section Mr JONATHAN HUTCHINSON's case recorded in the fifty seventh volume of the *Medico-Chirurgical Transactions* appears to have been the first successful case in this country, though one had occurred in France towards the end of the eighteenth century Since Mr HUTCHINSON's case in 1871 many others have been recorded, still failures far outnumbered successes and, indeed, laparotomy for intussusception had fallen into a certain degree of disrepute With the development of abdominal surgery the confidence of the surgeon in the comparative harmlessness of a laparotomy developed, and the abdomen was opened for the treatment of this condition with less and less hesitation. Still, however, the mortality continued high, and it was seen that no small share of the blame was to be attributed to the exhaustion produced by the previous attempts at reduction. Abdominal section was therefore gradually performed at an earlier stage, until it was found that the best results were obtainable in those cases where little or no previous attempts at distension had been made, and at the present time recourse to injection or inflation is gradually falling into disuse, and their place is being taken by laparotomy The results justify the change and the series of cases recently treated at the London Hospital, to which we have already referred, clearly demonstrate the value of a primary abdominal section in intussusception It is essential to distinguish in preparing statistics between secondary laparotomy, where the case has been previously treated by distension, and primary laparotomy, in which no other remedial measures have been employed. A confusion of these two classes will utterly vitiate the conclusions from any series of cases. The ease with which the invaginated gut can generally be withdrawn after the abdomen has been opened is truly marvellous, but in this, as in all other forms of acute intestinal obstruction, much depends on the duration of the symptoms and the tightness of the constriction If several days have elapsed and the inclosed bowel is tightly nipped, peritoneal adhesions will have fixed it and it may be impossible to withdraw it In such circumstances the prognosis cannot fail to be very grave whatever method of treatment be adopted. Fortunately these complications are exceptional, especially in cases treated early, and therefore we may hope for even better results with a growing recognition on the part of the public of the importance of early treatment.

May it then be said that distension should never be attempted? The treatment of an analogous condition strangulated hernia, will furnish the answer Formerly when a hernia became strangulated severe and protracted taxis was frequently employed for its reduction with disastrous results to the patient, now the routine treatment is an immediate herniotomy, but this may harmlessly be preceded by a single gentle attempt at reduction if the strangulation is recent. So is it too with intussusception. Laparotomy is the best method by which to treat this condition, but a single gentle attempt at distension in recent cases which are confined to the large intestine and not of an acute type may be performed with impunity One condition, however, is essential. The pressure in the colon must be absolutely under control, and this can only be effected by employing a liquid as the distending agent and using a funnel and rubber tube to introduce it. If the funnel be raised not more than two feet above the level of the patient the pressure will not exceed one pound on the square inch and this pressure is probably perfectly safe. The attempt should be made under an anæsthetic and should it fail laparotomy can be immediately proceeded with, while the surgeon will feel sure that he has not by this gentle distension impaired the chance of success of his operative procedure.

The Royal Dental Hospital and its Anæsthetists

THE entire staff of anæsthetists of the Royal Dental Hospital of London have been dismissed from their posts in circumstances which require consideration from us and we think that our readers will agree that the circumstances also require more consideration than they have apparently received from the committee of management of the well-known hospital in Leicester square. The story is briefly as follows —At the Royal Dental Hospital of London there has lately been appointed an officer—and doubtless he has proved a very useful officer—who is known as the dental superintendent. His duty we find in a recent report of the medical committee of the hospital defined as being "to supervise and direct the work of the demonstrators, the house surgeons, the curators, students, and pupils, and in the unavoidable absence of the anæsthetists to act as their deputy", and the same report adds that his appointment has proved an unmixed benefit to the hospital. In October of last year the dental superintendent presented a report to the committee of management of the hospital which is not in our hands, but which appears to have attributed want of regularity and punctuality in the exercise of their duties to some of the dental staff and some of the administrators of anæsthetics attached to the hospital This report was referred to and read at a meeting of the medical committee without any special notice of its contents being sent to the anæsthetists, who are, however members of the medical committee, and as a result a sub-committee was elected upon the suggestion of the medical committee to consider the dental superintendent's report. The sub committee was composed jointly of members of the medical committee and members of the committee of management, and reported to the committee of management "that having regard to the enormous increase in the number of gas cases the sub-committee is of opinion that the best way of dealing efficiently with the problem is by the appointment of two paid anæsthetists in place of the present honorary anæsthetic staff." The report also defined the hours of attendance of the medical staff and concluded thus —"that the members of the anæsthetic staff be thanked for their services and be made honorary governors of the hospital and that the two seniors be elected consulting anæsthetists to the institution." This last clause amounts, in our view, to dismissal of the anæsthetists of the hospital and, it may be noted, without any marked expression of gratitude for past services The report was adopted by resolution of the committee of management, without being submitted to the medical committee, and was at once embodied in a circular letter and despatched to the anæsthetists of the hospital, the majority of whom received it with complete surprise. Perhaps the anæsthetists may have been, as the sub committee's report comically calls them an "anæsthetic staff' not to suspect what was in the wind, but they did not. Some two years ago, at the time, we believe, that the dental superintendent was appointed, dissatisfaction was expressed with the way in which the anæsthetists rendered their services, but this had not prepared them for a dismissal *en bloc*, with only a formal word of thanks and no regretful phrase.

Such is the story There are several points of a personal nature which may arise in the discussion of this unfortunate affair, but we intend to do our best to consider the matter wholly on the broad grounds of the good of the public and of the dignity of the medical profession. The committee of management proposes to make an immediate alteration in the regulations of the hospital which we are quite ready to believe is intended as a measure of reform, but which seems to us to constitute a possible danger to the public and to display scant respect for an important body of medical workers There may or there may not have been irregularities in the attendance of the anæsthetists, but there can have occurred nothing to justify the immediate adoption of a report dispensing with their services in less than ten weeks from date. It is by the terms of his office no business whatever of the officer called the dental superintendent, to make reports upon the irregularities of the anæsthetists His duties appear to us to be clearly defined and distinctly arduous, and he should not have been asked to add to his duties that of noting, supervising, and directing the work of the anæsthetists of the hospital—for we take it that he was so asked and that he did not make his complaints upon his own initiative The one and only authority which would most certainly have been in the right in calling the attention of the anæsthetists to any lapse in their duties towards the hospital was, and is, the committee of management, and that committee has been apathetic up to the day when the dismissal of the anæsthetists was ordered. It is perfectly well known that the arrangements for the attendance of the anæsthetists at the Royal Dental Hospital have been under discussion at the hospital for many years, and from time to time rules have been framed by the anæsthetists themselves for dealing with the situation But the rules have not been kept by all the anæsthetists, and so, with the ever increasing work, the difficulty has become acute Any causes of dissatisfaction that the committee of management may have had ought to have been clearly expressed by that committee to the anæsthetists, and any failures in the system under which the anæsthetics have been hitherto administered to the patients must be laid to a great extent at the door of the authorities who have condoned all lapses by their attitude The authorities should have brought any reasons for complaint to the notice of the anæsthetists and should have insisted upon hearing any other side of the matter that might be presented. No vague and general expression of dissatisfaction could be expected to meet the case The arrangements for the attendance of the anæsthetists at the hospital have been criticised in a desultory way for a long time—we know that, but the committee of management has never discussed these arrangements with a view to tackle squarely any question that might arise if they were altered Suddenly, however, it resolves to discharge its anæsthetists, somewhat as an autocratic householder might rid himself of a body of insubordinate or dishonest servants, and we cannot regard its tactics as otherwise than a want of respect to the medical profession We shall be surprised to find that our readers regard the matter in any other light.

But there is another and more important reason than any we have yet adduced why the committee of management ought to desire to reconsider its action. By dismissing its staff of anæsthetists it proposes to overturn a system which, on the whole, has worked well for many years. To the success of the system by which the Royal Dental Hospital has been supplied with anæsthetists many of the best administrators of anæsthetics in the kingdom have contributed, and by so doing have provided for the safety of the public in a manner that the new arrangement can hardly promise to do Under the old system which, in accordance with the recent decision of the committee of management, comes to an end on March 1st of this year, the patients enjoy the services of specially selected and highly skilled anæsthetists. There has been great competition to obtain these posts and on the principle of the survival of the fittest they have been well filled. It is perfectly impossible to suppose that two paid anæsthetists can discharge the duties of the present honorary staff of anæsthetists Candidates of the position in their specialty filled by the present anæsthetists of the Royal Dental Hospital will not compete for paid appointments to be held under conditions of inferiority, and the posts will probably fall into the hands of junior and comparatively untried men. To the element of danger for the public thus introduced must be added another Two paid anæsthetists may not be able to stand the physical strain of work which has hitherto employed a certain proportion of the time of eleven experts The administration of nitrous oxide gas is not absolutely and always a simple matter It is only those who do not know how to administer "gas" who take this convenient and perilous view We would press these reflections on the committee of management of the Royal Dental Hospital The resolution by which it has dismissed its staff of anæsthetists does not take effect for a fortnight. In the interim we trust that the members of the committee will with unprejudiced minds think over the matter from the points of view which we have ventured to put very plainly before them By all means let the anæsthetists be called to order if they have erred Discipline must be maintained and the committee of management is the right body to maintain it. But let it not hurriedly overturn a system which guarantees a security for the public which will be wanting if the hospital has to rely for the future upon the services of two paid anæsthetists. We are certain that the medical profession and the public alike will think as we do. And we fear that if the committee of management persists in its proposed action without, at any rate, giving the whole matter that thorough re-discussion which its importance merits, it will endanger the prosperity of the institution for the good of which many of its members work so hard and so generously We do not ask the members of the committee of management to change their minds without reflection, we do not suggest that they should retain upon the staff of the hospital anyone with whose work they have reason to be dissatisfied, but we beg them to reopen the matter

Annotations.

'Ne quid nimis'

SMALL-POX IN THE PROVINCES

HAPPILY for us, the small pox epidemic, as far as London is concerned, may now be said to have been practically stamped out, only about three cases weekly having been notified in the metropolis since the beginning of the present year, but from official information just received we learn that the disease still continues to spread in some other parts of the country The Registrar General's return for the fourth quarter of last year, which has recently been published, contains a table (pp xxiii.-xxvi) showing the number of cases of dangerous infectious disease reported to the local authorities of the principal towns in England and Wales This table, which is a recent addition to the Registrar General's returns, is the natural and necessary complement to the ordinary tables of mortality from these diseases with which we have been familiar for many years past. The table referred to shows that although small pox was notified in the metropolis in only 43 cases last quarter, as many as 1477 cases of that disease in the aggregate were reported in 80 of the provincial towns included in the return. Although, if these attacks were evenly distributed over the entire English population small pox could not be said to have, as yet, attained epidemic proportions, nevertheless, the excessive incidence of the disease in Lancashire and Yorkshire, in parts of Staffordshire, and in South Wales, has been so pronounced as to cause considerable local anxiety We have selected from the lists of towns in the two counties first mentioned, a continuous infected area, largely composed of industrial communities, and containing a population about equal to that of London. In this area the incidence of attack by small pox last quarter was such that, if continued for a year, the ratio would approximate to one in each thousand of the population. In a group of urban districts in South Wales the proportion of notified cases to population has been only slightly less than this, whilst in a few towns in the Potteries, especially in Hanley and Walsall, the disease has been seriously prevalent and has shown a tendency to spread. Unfortunately, there are no recent returns to guide us as to how far the several populations are protected by vaccination or revaccination against small pox, but apart from this it is certain that in many of the smaller towns, at any rate the inhabitants are but very insufficiently provided with hospital accommodation in case of need. Consequently although in London almost every known case of small pox has hitherto been promptly isolated in hospital, in many of the provincial towns to which we have referred it is greatly to be feared that the majority of the cases will necessarily be treated at home and thus infection will practically be left to spread unchecked, until every susceptible person has been attacked. The town of Keighley, in Yorkshire, the inhabitants of which are well known to entertain peculiar views on the subject of vaccination, has suffered severely during the last three months, as many as 31 attacks having been notified there amongst a population scarcely exceeding 42,000 With the exception of a single case the borough of Leicester which is also notoriously opposed to vaccination, seems to have escaped infection up to the end of December last. We learn however from trustworthy sources that since the beginning of January a considerable number of cases have occurred in that town in consequence as it is stated locally of failure on the part of certain persons to report the earlier cases to the sanitary authority The proportion of unvaccinated children in the Leicester population is, we believe, very large, and although the local authorities are commendably assiduous in their attention to isolation and disinfection we shall be surprised if, sooner or later the town does not become the scene of a terribly fatal small pox epidemic Referring again to the new table (No VIII) in the Registrar General's return, we think that it should be in the hands of every medical officer of health and of every sanitary authority in the country In addition to the ordinary tables of mortality, which, by the way now relate to 179 of the chief English and Welsh towns instead of to the 83 towns for which particulars were formerly given the table now before us gives account of the prevalence of infectious disease (not necessarily fatal) in the above mentioned 179 towns, which may be taken as representative of every part of England and Wales The price of each quarterly return is only a few pence and, having regard to its unique value for preventive purposes, we are surprised that up to the present time its circulation has been so small as it is reported to have been.

A STRANGE ROAD TO ROYAL FAVOUR

HISTORY and tradition afford many curious instances of the unexpected way in which fame and practice have come to the medical practitioner In some cases it has been an act of kindness proffered to some apparently obscure and impoverished patient that has returned a thousandfold in the legacy of an eccentric millionaire, in others the bold outspoken declaration of some unpleasant medical truth has been rewarded by its hearer—conscious of the facts yet never before meeting a medical man who dared to state them—by constant adherence to, and influential recommendation of, the honest and unflinching medical adviser We doubt, however, if a practitioner has ever received a Court appointment through a more curious set of circumstances than those which, if report is true, have raised Dr Botkine to the position of Court physician at St Petersburg The Court physicians in Russia have hitherto been almost exclusively German. It appears that a short time ago, the Tsaritsa suffering from some affection of the throat, the Tsar summoned to her aid a Russian physician named Botkine. This gentleman requested Her Imperial Majesty to remove the wraps from her throat in order (we quote a daily paper) "to apply his ear so as to ascertain what was wrong with the larynx The Empress declined to remove the wraps, remarking that "up to now no doctors who had attended her had made such a request" Dr Botkine, we are told, had no other course open but to retire' The Tsar on hearing an account of the circumstances "made some remarks on the too obedient German physicians and appointed Dr Botkine Court physician" It is to be regretted that we cannot more generally reckon upon pleasing one person if we displease another, as seems to have been the result of Dr Botkine's action in this instance Possibly the Tsaritsa holds, as we do ourselves, that auscultation of the larynx is an unusual step in the case of a slight affection of the throat. At any rate, the result of her refusal will be a pleasant fillip to patriotic medical men in Russia

THE MEDICAL MISSION IN UGANDA

A GREAT misfortune has befallen the missionary hospital at Mengo, Uganda. On Nov 28th in the midst of a tropical storm the hospital was struck by lightning and within a few minutes the whole of it except the isolation wards and the dispensary was destroyed Fortunately no one was killed, though a patient with hip disease suffered a fracture of the thigh owing to a fall as he was being carried out. Most of the patients were able to run out of the burning building, among these were a woman with her newly-born babe, a patient on whom an ovariotomy had recently been performed, and two men who had just undergone radical cure for hernia, and none of them appear to have suffered any harm from their sudden removal into the downpour of a tropical storm. The Baganda, who thoroughly appreciate the benefits of the hospital, made most strenuous exertions to save the patients and the contents, but unhappily much was destroyed A fresh supply of instruments with two new instrument cupboards of plate glass had been unpacked only the day before, and these were nearly all destroyed, but it was found possible to save some of the instruments. Two native helpers succeeded in rescuing two microscopes but did not bring away the higher powers, perhaps thinking that such small objects could not be of any great importance Such an accident is a dire misfortune to a flourishing medical mission such as that at Mengo The medical officers are Dr A R. Cook and his brother, Mr J H. Cook The hospital contained 70 beds and during 1901 had 1070 in patients, and out-patients made 76,840 visits It will thus be seen that a great work was being done in this hospital which was only built in 1899 It is hoped to rebuild it of much less inflammable material, and this is now possible as the railway has reached the lake, and corrugated iron roofing and concrete are comparatively cheap The natives have promised assistance and will provide the 400 000 bricks required and all the timber The new hospital will have accommodation for 100 beds. The commissioner has supplied free of all expense 400 men to assist in building a temporary hospital and some other local help has been obtained, but there is great need of extraneous assistance, both for rebuilding the hospital and for providing furniture, stores, and instruments We feel sure that this assistance will be forthcoming as soon as the merits and needs of the medical mission are known We would make one suggestion Thunderstorms are, we are told, extremely frequent in this part of Uganda, it would be well, therefore to see that the new hospital is provided with lightning rods Doubts have at times been expressed as to the value of missionary efforts, but whatever conclusion may be arrived at with regard to missions generally we do not believe that anyone will deny the vast extent of the good done at medical missions To any medical man who has travelled in the east the need for skilled treatment of the suffering millions is apparent. Diseases readily amenable to our treatment are endured for years and suffering and death are rampant. The work of the medical missionary in relieving this suffering is good and we earnestly hope that it may flourish more and more.

THREE DISTINGUISHED AMATEUR PHYSICIANS

THE above is the title of a paper read by Dr W S Colman before the Medical and Physical Society of St. Thomas's Hospital on Oct 16th, 1902, and reprinted from the *St Thomas's Hospital Gazette* Dr Colman is more courteous in his title than in the commencement of his paper, for after alluding to a predecessor of his who had given an address upon some eminent surgeons he continues, "I am going to deal with some eminent quacks." We must premise that Dr Colman's "amateur physicians" were Charles II., Valentine Greatrakes, and John Wesley Now we consider that a quack is a person who pretends to be able to cure sufferers and who always takes fees for his work or drugs Typical quacks are the Viavi Company and people of the type of "the Revd " Joseph Hope or "Dr " Bell. But we do not think that any one of the three unqualified practitioners mentioned by Dr Colman could be written down simply as a quack. To commence with Charles II All sovereigns of England from Edward the Confessor down to Queen Anne, with the possible exception of William III, considered that they were divinely commissioned by the Almighty to be able to cure "scrofula" by the royal touch. They were, we know, mistaken, but still they were not quacks There was a special service appointed for the "touching," and it was printed in the Book of Common Prayer down to the end of the eighteenth century "There is no doubt," says Dr Colman, "that many cases received benefit. Many of these we should now class as faith healing, but in other cases the good result may well have followed the cessation of the nasty messes which were then in vogue as dressings, since it was considered respectful to keep the part which the king had touched simply covered with a fair linen cloth " Dr Colman, by the way, says that the touch piece which was hung round the patient's neck was nearly always a gold angel. This was so, we believe, up to the end of the reign of Charles I., when the issue of "angels" was discontinued Subsequently special "touch pieces" were struck for the purpose. Although smaller in size (and their size varied) the "types" both of the obverse and the reverse were similar to those of the angel Valentine Greatrakes and John Wesley more nearly deserve the name of quacks than did the Royal "healers." The former was an Irish gentleman who was born in 1601 and who, after the Restoration, was persuaded that there was bestowed on him the gift of curing the King's evil. His method of treatment was by "stroking," and no doubt he relieved certain functional disorders by a combination of massage and hypnotism He charged no fees, but in one case at least, an unsuccessful one, he charged his expenses John Wesley, better known to fame as the founder of the Methodist body was an ignorant practitioner but at least a sincere one. He noted in his missionary journeys that the poor were badly supplied with medical advice and that even when they did obtain it it was grounded upon irrational principles Unfortunately, though having no medical education, he considered himself qualified to write a book upon treatment. Dr Colman allows that he was sound in maintaining that general hygienic treatment was as important as drug treatment, but still his book was full of absurdities, and even dangerous ones, as when he advises four grain doses of perchloride of mercury for fistula. But he made no charge for advice, although he did for his book, and then the profits were given to charity, moreover, if the patient suffered from a complication of disorders he says, "You would do well to apply to a physician that fears God' There was some excuse for both Greatrakes and Wesley Medical science in their day was crude, communication was difficult, and hospitals were few There is no excuse nowadays for the amateur physician, whether he be a parish priest who pretends that nine minims of carbolic acid will cure influenza, or for the inmates of a religious house who sell salves warranted to cure almost anything

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE

THIS Congress will take place at Madrid from April 23rd to 30th, 1903. The final programme is being prepared The committee invites members to send to the secretary general (Dr A F Caro) at Madrid, as soon as possible, the *titles of* their communications accompanied by an extract (or *résumé* in the form of conclusions if possible), preferably in French All extracts which reach the secretary in time will be printed and sent before the opening of the Congress to the members of the respective sections in order to facilitate discussion during the Congress. In addition to the reduced rates for transport announced in THE LANCET of Sept 6th, 1902, p 693, the following are now announced France, Compagnie de Navigation La Transatlantique, Compagnie Mixte, and Transports Maritimes, 30 per cent, Italy, Italian railways (Mediterranea, Adriatica, and Ferrovie Sicule), 50 per cent, and Norwegian railways, Roumanian railways, and Servian railways, 50 per cent. At Madrid from April 3rd to May 24th special tickets at the same reduction of 50 per cent. will be issued to enable the different towns in the south of Spain (Seville, Granada, &c), to be visited, and it is probable that holders of these tickets will not be obliged to return to Madrid on leaving Spain. Such tickets will only be obtainable at the booking offices at the time of the excursions upon presentation of a card of identity which will be sent to every inscribed member Full programmes of these excursions can be obtained from the Voyages Pratiques, 9, rue de Rome, Paris, or in London at 11, Ludgate hill (Messrs. Seelig and Reed, Limited.) The Service des Logements denies the reports which have been circulated as to the difficulty or impossibility of obtaining convenient lodgings during the Congress. It is true, we are informed, that some of the better known hotels have been besieged with demands, but at Madrid there are a large number of other hotels which, though not so important as the Hotels de la Paix, Rome, Paris, &c., are in no way inferior in comfort and cooking. In addition the committee has secured thousands of lodgings in first-class private houses and many French, German, and other families have offered to receive one or more persons. The Service des Logements can therefore always procure a complete pension from 13 pesetas to 50 pesetas per day. The definite distribution of accommodation will not take place until the month of April, but in order to make sure of being well lodged demands should be made now to Mr. Ulrich Frei, Service des Logements du XIVe Congrès International de Médecine, Madrid. Grand fetes will be organised at Madrid in honour of the members of the Congress. Their Majesties will give a garden party and a general reception at the palace, and the municipality is organising a general fete and probably a special play at the theatre. There will also be a *corrida de toros* in addition to which the different sections are organising special fetes and excursions limited to the members of such sections. The definite programme will be communicated later to all interested. Subscriptions (25 francs, by cheque on Paris) may be addressed to the secretary-general at Madrid, or up to March 20th to the national committees of the various countries. Other particulars will be found in THE LANCET of Oct. 18th, 1902, p. 1070 and Dec. 13th, 1902, p. 1642. The honorary secretaries for Great Britain and Ireland are Mr. D'Arcy Power, 10A, Chandos-street, London, W., and Dr. P. Horton-Smith, 15, Upper Brook-street, Grosvenor-square, London, W.

THE DIAGNOSIS OF NEURASTHENIA.

CONSIDERABLE progress has been made in recent years in our knowledge of neurasthenia as regards its more minute clinical and diagnostic features, and the term as now used possesses a far more precise clinical and neurological significance than it did at the time when Beard of New York recorded his pioneer work on the subject. Professor Emil Kraepelin of Heidelberg has published in a recent issue of the *Münchener Medicinische Wochenschrift* (No. 40, 1902) an important article in which an attempt is made to define clearly the precise character and the limits of neurasthenia in the interests of diagnosis and treatment. Many nervous diseases, says Professor Kraepelin, may, at various stages of their development, simulate neurasthenia. One of the most important of these is general paralysis of the insane at its earlier stages. If a characteristic tremulous and paretic speech and oculo-pupillary disturbances in the form of inequality of the pupils with loss of the direct and consensual light reflexes are present, the co-existence of these with neurasthenic symptoms will point to early general paralysis rather than to neurasthenia proper. Moreover, the occasional occurrence of a maniacal outbreak will serve to distinguish general paralysis from neurasthenia when the diagnosis is for a time difficult. Some forms of dementia præcox—the precocious dementia of adolescents—are, it is pointed out, liable to be confounded with neurasthenia, and this is especially true of the hebephreniac form. The occurrence of positive mental deterioration and the presence of hallucinations will serve to distinguish the latter from neurasthenia. It is important to discriminate between neurasthenia and the degenerative psychoses of adolescence since useless and expensive efforts to obtain a cure by means of hydrotherapy, electricity, and hypnosis need not be made or disappointment incurred if it is known that the case is one of dementia præcox and not of neurasthenia. The development of any one of such symptoms as stupor and mental automatism, muscular hypertonicity, stereotyped oddities of posture and movement, and "negativism" or a passive resistance to everything that is required to be done by the physician or nurse should lead to the suspicion of dementia præcox and not of neurasthenia. There is moreover a group of mental disorders termed by Professor Kraepelin "manic-depressive insanity" which in their prodromal stages may be confounded with neurasthenia. On careful investigation of the clinical history and psychical condition of such patients there will be detected one or more of the following symptoms which sometimes are found in neurasthenia but which in their more intense or extreme developments are present in the group of insanities alluded to—viz., marked weariness or prostration (*Abgeschlagenheit*), incapacity for work, gloomy disposition, hypochondriacal apprehensions, cephalic paræsthesias, insomnia, and disagreeable sensations (including feelings of weight) in the limbs. In cases of insanity amelioration of these symptoms will occur sooner or later, since the psychoses of the "manic-depressive" group are characterised by symptoms which fluctuate considerably and periodically, whereas in neurasthenia such symptoms are more constant and less severe. Neurasthenia is usually, adds Professor Kraepelin, a slowly progressive state which diminishes the patient's capacity for work and mental application. Such patients may be spurred on by relatives to put forth greater efforts to overcome their weakness with the result that the malady invariably becomes aggravated. Many neurasthenic patients are thus driven to take stimulants such as alcohol or morphia, the latter being especially employed owing to the feeling of well-being and of heightened capacity for work and action that it promotes, and eventually such a patient becomes a drunkard or a morphinomaniac. The bodily processes of nutrition are perverted in neurasthenia and there is defective excretion of the waste products of tissue metabolism, while the nerve tissues exhibit a deficiency in the capacity for recuperation of energy during rest or sleep. A limited class of cases of neurasthenia, says Professor Kraepelin, may be the outcome of sudden and severe disturbance of the nervous system such as is caused by traumatism and physical shock as in railway accidents. Sudden fright without physical shock may also be a cause. Some of these cases are of grave prognosis. A large and important group of neurasthenias has a congenital origin and shows a close affinity to hypochondriasis on the one hand and to the insanities of morbid doubt and scruple (*Grübelsucht*) on the other. Those cases which belong to the category of insanity as distinguished from neurasthenia will be manifested by occasional outbreaks of great mental perturbation or of dangerous impulses towards homicide, crime, or suicide. The term "neurasthenia," concludes Professor Kraepelin, is, even at present, used loosely to include many psychoses as above mentioned, but its meaning should be restricted so as to exclude the latter which really belong to the category of mental alienation or insanity. A separation and classification of these types of mental disorder will lead to a more discriminating diagnosis and to a more satisfactory treatment of cases of neurasthenia as well as of these psychoses.

CHOLERA IN EGYPT.

DURING the week ending Jan. 19th there were 4 fresh cases of cholera at Alexandria and 3 deaths. Only one patient remained under treatment at the end of the week. These were all the cases in Egypt during that week and during the preceding week neither attacks nor deaths were registered in Alexandria. With reference to the outbreak at the small village of Khoos-el-Bousa mentioned in THE LANCET of Jan. 10th, p. 115, later information received from Egypt is to the effect that Mr A. T White of the medical department, assistant inspector of Upper Egypt, immediately carried out the sanitary precautions which resulted in the suppression of the epidemic Dr C Goodman and his staff of well borers arrived three days after Mr White During the week ending Jan 26th neither cases of, nor deaths from, cholera were reported throughout Egypt During the previous week four cases of cholera were notified at Alexandria, the last case occurring on Jan. 18th

THE SMOKE NUISANCE IN LONDON

THE Battersea borough council is to be congratulated upon having secured a decision from a police magistrate, Mr. Garrett, against the London, Brighton, and South Coast railway company for permitting a smoke nuisance It arose through the company's practice of firing their engines in a shed or covered way at Victoria road, Battersea, the smoke arising in the process being allowed to escape through funnels in the roof The defence was raised that these funnels were not chimneys within the meaning of the Public Health Act under which the proceedings were taken The magistrate held that they were and expressed himself satisfied that with care and some inconsiderable expenditure of money the nuisance complained of might be satisfactorily abated. He inflicted a small fine which no doubt will have the desired effect.

URÆMIC ULCERATION OF THE DUODENUM

URÆMIC ulceration of the duodenum was first described by Wilks and Moxon in their "Lectures on Pathological Anatomy," published in 1875 They pointed out the frequency with which ulcers of the stomach and duodenum were found in Bright's disease. In the Guy's Hospital Reports for 1893 Dr E C Perry and Dr L E Shaw published an important paper on diseases of the duodenum in which they described a number of cases of ulcer in Bright's disease But the literature of the subject is still very scanty At the meeting of the Société Médicale des Hôpitaux of Paris on Jan. 16th M Ernest Barié and M Paul Delaunay related the following case. A man, aged 52 years, who was addicted to alcohol, was admitted to hospital on August 29th, 1902 15 years before he contracted syphilis For two months he had suffered from breathlessness which at times culminated in attacks of dyspnœa. Digestion was painful and he often vomited his food There were symptoms of pulmonary emphysema and moist râles The urine contained albumin and the legs were œdematous On Sept. 15th pericardial friction was heard, on the 19th it had disappeared. On the 22nd diarrhœa began, and on the 23rd there was abundant enterorrhagia the mattress being soaked with blood On the next day he became comatose and died. The necropsy showed in the brain the remains of an old hæmorrhage and atheromatous arteries. The lungs were emphysematous and œdematous On the visceral pericardium was recent fibrin, the left ventricle was hypertrophied. The whole colon was full of blackish brown blood, but its mucous membrane showed no ulceration The second half of the small intestine was almost empty, the first half contained bile and a little blood, the whole mucous membrane was congested and covered by the viscid adherent mucus which has been described by Treitz in intestinal uræmia. In the duodenum, two centimetres from the pylorus, was an oval ulcer one and a half centimetres in diameter At its base the circular muscular fibres of the intestine were seen. Two centimetres below this ulcer was a smaller one half a centimetre in diameter, and three centimetres further down in the intestine, opposite the ampulla of Vater, were two still smaller contiguous ulcers. The kidneys were granular, Uræmic ulceration of the duodenum generally takes the form of a single ulcer in the first part of the duodenum, but there may be two or more ulcers Sometimes the remaining part of the duodenum has been found intact and sometimes inflamed. The remaining part of the alimentary canal also may be inflamed or present similar ulcers and the glairy adherent mucus mentioned above The symptoms are inconstant. Sometimes a subject of renal disease in apparent health is seized with symptoms of perforative peritonitis Sometimes the symptoms occur during uræmia there may be epigastric pain two or three hours after a meal, vomiting, diarrhœa, melæna, and, much more rarely, hæmatemesis Duodenal ulceration occurs in the most diverse renal diseases—acute and chronic parenchymatous nephritis, interstitial nephritis, ascending nephritis, peri renal phlegmon in renal lithiasis, and renal tuberculosis As to the pathogenesis of the duodenal ulceration several explanations have been advanced. The most reasonable seems to be that defective renal secretion leads to vicarious excretion by the alimentary canal. Hence the stomatitis, dyspepsia gastralgia, vomiting, and diarrhœa of uræmia Why the duodenum should be specially affected seems difficult to explain But Stassano has attempted to show that the duodenum plays a special part in the excretion of poisons. He found that mercury was excreted by leucocytes into the alimentary canal—slightly into the stomach, more into the intestine, and most into the duodenum.

GRASS AND PHOSPHATES

WE have received a copy of the Report upon the Utility of Superphosphate as a Top Dressing for Grass lands issued by the Chemical Manure Manufacturers' Association, the perusal of which we commend to every well wisher of his country The *brochure* is well headed by the celebrated quotation from Dean Swift about 'two blades of grass where one grew before" which deserves to be written in letters of gold. It is pleasant to see the modern agriculturist turning for encouragement to that staunch patriot who was to the last hour of his life passionately devoted to the interests of his fellow men We venture to think that the whole subject of phosphates, which has such an important bearing on the question of food supply is of national importance and has been far too much neglected by thinkers and statesmen. There can be no doubt whatever that the soil of the country has been more or less denuded of this vital constituent, the system of grass farming now prevailing having apparently had much to do with this mistaken policy, some farmers thinking that when land is devoted to grass cultivation little beyond farmyard manure is required, forgetting that each crop makes a heavy demand on the mineral ingredients of the soil. It seems worthy of notice that though nitrogen and potash are of great importance as fertilisers they are to some extent supplied naturally—the nitrogen from the air and potash from the inexhaustible inert matter of the earth—but phosphate once gone can only be replaced by the hand of man The reaction by which superphosphate is made (mono-calcic phosphate) was discovered by the celebrated agriculturist Sir John Lawes, and the manufacture has been principally carried on by the company founded by him ever since with great success and with immense benefit to the country Several efforts have been made "to improve" on superphosphate, but they appear unsatisfactory and ill judged, and superphosphates, the active and available combination of vital phosphorus, in every sense emphatically "holds the field.' An important committee has been recently formed to study the question of food supply in time of war Might we urge on its members to consider the question of artificial manures? Surely it would be easier to import in such circumstances of stress as occur in war time the essential elements of our food supply rather than vast shiploads of the harvested cereals. Besides, the question of work for the unemployed, now so painfully in evidence in the streets, would at the same time be to some extent solved by the increased demand for men to till the land. We cannot, however, go into this, but again commend the study of this pamphlet to our readers. Medical men are not uninterested in this matter The wise and benevolent physician will readily admit that a fertile country and a well nourished nation will tend to what no one wishes more to see than he does himself—the vigour, strength, and happiness of mankind.

THE DISTRIBUTION OF PLAGUE

AS regards Egypt, 7 cases of plague have occurred at the village of Barshoum el Koubra, Toukh District (Galioubieh Province), during the week ending Jan. 25th. Of these 3 proved fatal. Since Nov 19th last no cases have occurred at Alexandria. The reappearance of the disease is probably due to infection which has been lying dormant since last year amongst rats that may have migrated from the village of Sayafa which is almost contiguous and where plague occurred during last summer It is possible that similar outbreaks may occur in or near towns or villages where existed plague last year Such towns and villages are being carefully watched. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Feb 6th states that for the week ending Feb. 5th there were 5 cases of bubonic plague and 4 deaths from the disease. As regards the Cape Colony the medical officer of health for the colony states that for the week ending Jan 17th no case of plague in any human being has been discovered at any place in the colony At the end of the week 1 case remained under treatment at the plague hospital, Port Elizabeth. Plague-infected rats have been found in Port Elizabeth during the week, the last being discovered on Jan. 15th. As regards Hong Kong a telegram from the Governor received at the Colonial Office on Feb 10th states that for the week ending Feb 7th there were 12 cases of bubonic plague and 12 deaths from the disease.

THE MENTAL CHARACTER AND THE TREATMENT OF THE EPILEPTIC

AN interesting symposium dealing with the mental character and treatment of the epileptic is contributed by various writers to the *Journal of the American Medical Association* of Jan. 17th. Dr H. A. Tomlinson, medical superintendent of the Minnesota State Asylum, pointed out that a special condition of irritability and instability of the cerebral cortex characterised all epileptics. Apart from causes acting in infancy, such as the irritation felt during dentition the epoch of puberty often served to disclose an epileptic taint latent in childhood. One of the main sources of danger to the epileptic arose from the conditions of the gastro-intestinal canal. The epileptic as a rule masticated food very slightly and was inclined ' to bolt " it Gastro-intestinal fermentation and indigestion were thus readily set up and the reflex irritation communicated from the stomach *viâ* the pneumogastric nerve increased the excitability of the brain and caused fits ' to appear with undue frequency Psychologically the epileptic was, as a rule, a dullard and few were brilliant Epilepsy tended to dull the finer sentiments and to exaggerate the brutal and primitive instincts of man. The epileptic frequently exhibited low cunning and a lack of moral sense while he was often ostentatiously religious. When states of stupidity or of mental automatism occurred in epileptics after fits the question of responsibility for acts done in such states might be raised, as dangerous acts and crimes were known to be perpetrated by epileptics under such conditions. Professor Daniel Brower of Rush Medical College stated that epileptic children were liable to fits of ungovernable passion Physical training should be the main employment of the epileptic child. All indigestible foods, such as pork, veal, nuts pickles, and pastry, should be forbidden, and stimulants in the shape of beer wine, or spirits should never be allowed. Sugar and salt should be given but little, indeed, it was best to avoid seasoning with salt the food taken by epileptics as the therapeutic effect of the bromides given as medicine was enhanced thereby The bowels should be kept open regularly with aperients such as blue pill and black draught A little salol given from time to time for intestinal asepsis was valuable. Dr William Spratling medical superintendent of the Craig Colony for Epileptics, New York, pointed out that to get the best results of treatment three kinds of institutions were required—viz., first, asylums or hospitals for insane epileptics, secondly, industrial colonies for selected cases of epileptics who were feeble minded or imbecile, and, thirdly, similar colonies for all epileptics who were not insane. In practice the last two classes of cases could be housed and treated in one institution with success At Craig Colony where this was the custom it was found that 50 per cent of epileptics could do remunerative work. Dr F S. Pearce spoke regarding the excellent results of hydrotherapy and of the administration of digitalis in epileptics with a feeble heart and circulation Dr Frank Norbury cited six or seven cases of nocturnal epilepsy, in which the fits occurred only at night and which appeared to benefit by the mixed treatment of borax and bromide. Professor Charles K. Mills of Philadelphia regarded the industrial colony as the ideal home for the epileptic. He found a mixture of bromide with conium or sometimes with digitalis to be most useful Dr Spratling said that among his cases of epilepsy at Craig Colony 15 per cent were due to alcoholism in the parents, 14 per cent. to tuberculosis, and 10 per cent. to insanity in the parents while 16 per cent. had epileptic parents A strong hereditary origin could thus be traced in 55 per cent of cases of epilepsy

STRANGE SUICIDES IN BED

IN a leading article in THE LANCET of Oct. 5th, 1901, p 921 we drew attention to the peculiar methods which persons have adopted for putting an end to their lives. Cases occur from time to time in which the fatal act is committed whilst the victim of self murder is in bed. Mr Troutbeck recently held an inquest as to the death of a patient named Joseph Green who was in King's College Hospital A lad who was a patient in the same ward noticed that Green was acting strangely There were movements under the bed clothes as if Green were stabbing himself in the abdomen, and he subsequently pulled the clothes up level with his eyes and seemed to be injuring his face. On examination a wound eight inches long was found in the abdomen and an incision seven inches long on the left side of the neck. He died the same night. Suicide by hanging has occasionally been accomplished in bed. A case is recorded of a girl who thus killed herself by merely securing a cord to the frame of the bedstead and then leaning back in bed, the tension so produced being sufficient to cause the necessary constriction of the neck. Two other girls who were sleeping in the same bed were not awakened. Another strange case is that of a woman who laid herself on a bed attached the running noose of a rope round her neck, tied the other end of the rope to a heavy piece of metal which she threw over the iron bar of the bed frame, and was thus strangled. A singular case is recorded of suicide by throttling A woman, aged 40 years, suffering from melancholia, who had previously made several attempts to commit suicide, was found dead crouched in bed with both hands compressing her throat, the elbows were supported on the knees and the back leaned against the wall. There were marks of her finger nails on both sides of the throat. Suicide by smothering is also rare, but an instance occurred in France in which a woman placed herself under the bed-clothes after desiring her little child to bring all the cushions, clothes, and other similar articles that were in the room and to pile them on top of her The child did so and some hours afterwards the woman was found dead. A woman in an asylum, aged 38 years, was found early one morning dead in bed with part of a stocking protruding from her mouth, death having resulted from suffocation No noise or disturbance was noticed by other patients who slept in the same ward. At the inquest a long stocking was exhibited which with great difficulty had been removed from the air passages As a final example of strange suicides whilst in bed we may refer to the case of a maid servant who was found dead. The body lay at full length, with the head turned a little on one side, the arms crossed over the trunk, and the bed clothes pulled up smoothly to the chin. Under the clothes, on her right side lay a corked phial which was wrapped in paper and contained three and a half drachms of hydrocyanic acid. From the size of the bottle it was probable that four and a half drachms of the poison had been swallowed and the question arose, could the girl after taking this quantity of the poison have corked the bottle, wrapped it up, and adjusted the clothes? A man was suspected of having murdered her, but as several cases were quoted at the trial showing that in other instances of undoubted suicide similar acts had been performed the prisoner was acquitted. Such cases afford considerable difficulty to jurists and no general lines can be laid down for their elucidation, each case must be considered in detail as it occurs.

ANTE-NATAL RIGOR MORTIS

AN interesting query has been addressed to us by one of our correspondents. Does rigor mortis occur in healthy, full term, still born children? Our readers will not be surprised to learn that this interesting question of ante-natal pathology has been very fully discussed by Dr J W Ballantyne.[1] He has collected and analysed some 25 cases of ante-natal rigor mortis. Although Casper in his text-book on Forensic Medicine stated that he had never seen an instance of cadaveric stiffening in the premature fœtus, yet the occurrence of such a condition is beyond dispute at the present day and in the more recent text-books of forensic medicine it is admitted to occur According to Dr Ballantyne the first case of ante natal rigor mortis is probably that of Chowne,[2] which was originally recorded in THE LANCET Since this cases have been published in our columns by Dr R. Boxall[3] and by Dr B Jones.[4] There is, indeed, nothing in the surroundings of the fœtus in utero incompatible with the occurrence of this condition, and the presence of the liquor amnii only produces a state of things analogous to that met with in the case of a person found drowned, and, indeed, ante-natal rigor mortis has been conclusively demonstrated by J Tissot to take place in fœtal kittens. It has further been pointed out by Dr Ballantyne and others that there are no essential differences between the cadaveric rigidity of the still born infant and that occurring at other ages. It might naturally be expected that differences would be found in the degree of severity of the stiffening due to the varying time of the occurrence of the death of the fœtus and to its cause which must of necessity vary very largely in different cases That the condition has not been more frequently observed is, no doubt, due to the fact that it has not been looked for, and to the further fact that it may have occurred and passed off in utero In the case of patients dying gradually rigor mortis comes on very early and passes off very quickly and this may well be so in some instances of fœtal death That rigor mortis does occur in utero has been proved by its presence in cases treated by Cæsarean section. The case recorded by Dr Boxall is one of great clinical interest, because the course of the labour was apparently prejudicially influenced by the undue rigidity of the fœtus interfering with the normal mechanism of delivery The subject is one of great interest and further observations upon it cannot fail to prove of value both from a clinical and medico legal point of view since, as Dr Ballantyne truly points out the occurrence of rigor mortis alone does not suffice to show that the infant was born alive in the legal sense of the term

IMMIGRANTS INTO THE UNITED STATES

DURING the year 1902 551,645 aliens landed at the port of New York. This breaks all records since 1819 when the authorities began to register immigrants from the Old World into the United States The nearest approach to the total for 1902 was in 1882, when 476,086 foreigners were landed at Castle Garden, and 1892 comes next with 445,989 This would indicate that the tide of immigration reaches its height every 10 years. In 1901 408,040 aliens passed through the Ellis Island Bureau and 341,712 in the previous year In 1854 319,233 immigrants arrived at New York and 213,736 in 1849 The percentage of deportations for mental or physical infirmity or poverty was also greater during last year than in any previous year The records show that out of 36,600 arrivals during December 900 were excluded, while for the same month in 1901 there were only 255 exclusions out of 29,685 arrivals. Of the total number landed during 1902 5533 were ordered to be deported, liability to become a public charge being the chief cause of exclusion. The increase in the number and percentage of deportations is due to the more rigid examination of immigrants which has been a feature of the present commissioner s administration. The work in connexion with the strict inspection has been so severe that in the past month four inspectors have handed in their resignations The various steamship companies were forced to exercise a stricter supervision over the class of steerage passengers who arrived in their vessels and to be more careful in making out their manifests, as fines ranging from 10 to 1000 dollars per steamship were inflicted upon the companies guilty of careless or improper manifestation.

CEREBRO-SPINAL RHINORRHŒA AFTER FRACTURE OF THE SKULL.

DISCHARGE of cerebro spinal fluid from the nose is a rare symptom of fracture of the base of the skull In the *Liverpool Medico Chirurgical Journal* for October, 1902, Mr F C Larkin has pointed out that this discharge may exist some time after the fracture when the patient has apparently recovered, a comparatively unrecognised fact. He relates the case of a man, aged 21 years, who on Nov 19th, 1901, fell a distance of 15 feet on his face, lost consciousness, bled from the nose, and vomited. He was removed to hospital where concussion of the brain was diagnosed. He regained consciousness in a couple of days and then complained of deafness On the fourth day there was left purulent otitis which lasted about a week. After another week the only symptoms were slight deafness and occasional headaches As he felt quite well he would not remain in bed and went home on Dec. 10th On the 12th he appeared among the out-patients and said that he was quite well, but his handkerchief was saturated with moisture and he repeatedly wiped his nose. He had first noticed the discharge on the 9th when he sat up in bed for the first time after the accident. On being made to stoop clear watery fluid flowed from the nose, principally from the left nostril. With difficulty he was persuaded to re-enter the hospital. Next morning he complained of severe frontal headache and the flow had stopped. The temperature was 102° F and he began to be heavy and stupid. Unconsciousness and symptoms of meningitis followed and death took place on the twenty seventh day after the fall The necropsy showed meningitis, several fine cracks in the frontal bone, and a slit in the basi sphenoid three-quarters of an inch long and one sixteenth of an inch wide, through which a fine probe could be passed into the nose. The posterior end was close to the pharyngeal end of the left Eustachian tube Mr Larkin thinks that the deafness and otitis were probably due to pressure on the Eustachian tubes from swelling of the parts. He refers to another still more remarkable case previously recorded by him in which fracture of the frontal bone extending into the fronto-ethmoid region resulted from a bicycle accident. The patient recovered from the injury and resumed work but was much annoyed by a watery discharge from the nose This suddenly stopped six weeks after the accident. The patient seemed quite well but occasionally complained of frontal headache. Nine months after the accident he died from meningitis Only one other case of cerebro-spinal rhinorrhœa after fracture of the skull in which the diagnosis was verified by necropsy has been recorded In this one, reported by Bosworth, there was a fracture of the cribriform plate of the ethmoid and death occurred on the eighteenth day after the injury In neither of the cases recorded by Mr Larkin was there any attempt at union of the fracture through the thin scaly bones He suggests that cerebro-spinal rhinorrhœa often occurs after fracture of the skull and is unnoticed. Patients with fractured skull being kept very quiet in the recumbent posture the escape is probably small and the fluid is swallowed The treatment which he recommends is to keep the nose as sterile as possible and the patient recumbent in bed in the hope that protective adhesions may form before infection occurs. Tillaux has described a case in which discharge of cerebro-spinal fluid from the nose resulted from the forcible removal of polypi and continued off and on for six years until the man died from convulsions.

THE EFFECT OF AGITATION UPON THE MICROBE

MOST germicides are more or less poisonous to the human organism and therefore the destruction of bacteria in food and drink by the addition of powerful antiseptics is not available. It is well known, however that certain physical agencies exert a germicidal action, as, for example, light, electricity, and heat, and to these must be added the curious influence of mechanical shock. According to a number of interesting experiments on this point there can be little doubt that the vitality of lower organisms is influenced by agitation, even to the extent of total destruction. Thus by submitting to violent agitation certain bacterial cultures it has been found that the number of germs diminished to less than one-tenth of that originally present. Ultimately, by prolonging the treatment, the liquid was entirely freed from active germs and failed to develop further organisms, even when placed under favourable conditions By adding some glass beads to the bacterial culture the effect was more prompt, the liquid rapidly becoming sterile. In another experiment bacterial cultures were allowed to stand in an engine-room of a large manufactory in which an incessant vibration was produced by the strokes of the engine with the result that after four days the vitality of the germs was completely destroyed, while in the control samples which were left in a quiet place the germs, it was found, had retained their activity It would appear from this interesting experiment that minute vibrations have the power of hindering the growth of micro-organisms as well as violent shocks, while if either treatment be continued the germs at length die. The reason why the vitality of the cell is thus cut short is not quite clear but apparently the cells cohere and form a palpable powder Further experiments in this direction would be very interesting with the view of determining as to how far the process would be effectual in regard to the destruction of microbes in food. At the present time the oyster trade would welcome such a method could it be shown that it effectually destroyed the bacilli of the colon series in the oyster without disturbing its structure or spoiling its flavour In which case the guaranteed "agitated native" would be in brisk demand. The shaking, however, would have to be severe, no less than 180 reversed movements per minute over a distance of 15 inches being necessary

AN EXEMPLARY SENTENCE FOR CRUELTY

A CASE of child farming which was recently decided at the Middlesex Quarter Sessions is remarkable in more ways than one. The accused were persons living in comparative comfort, a retired clerk, his wife and daughter, with a total income of about £160 a year They had under their care no fewer than nine children, the eldest aged seven years and the two youngest 10 and 11 months respectively With most of these children sums of money varying from £10 to £30 had been received The two infants were kept in a rush portmanteau without either bedding or covering save a linen cloth The weather when the "baby farm" was broken up was bitterly cold. The other children were very insufficiently clad and slept on the floor without bed or covering All were half starved and ravenously hungry with the exception of one who was stated to be the daughter's child and appeared to be comparatively well-cared for In the face of such facts as these a conviction was inevitable, and we are not sorry that it was accompanied by the exemplary sentence of three years' hard labour in the case of each offender The children were taken into the workhouse. The credit of discovering this den of wickedness and misery, and of tracking its proprietors under changes of name and residence till their apprehension, belongs to the National Society for the Prevention of Cruelty to Children. There was a more or less overt attempt made on the part of the defendants in this trial to impute an excess of zeal to the agents of the society, but without success. The presiding justice had fortunately no sympathy with this view , on the contrary he took occasion to note the absolute fairness which had marked the proceedings of the society in all cases conducted by it which had come under his observation

FOOD POISONING AND EPIDEMIC DIARRHŒA

SEVERAL important questions bearing on the mutual relations of food poisoning and epidemic diarrhœa engaged the attention of the Epidemiological Society at its two last meetings held on Dec 12th, 1902, and Jan. 16th, 1903. Professor Sheridan Delépine introduced the subject with a paper on the Bearing of Outbreaks of Food Poisoning upon the Etiology of Epidemic Diarrhœa After defining epidemic diarrhœa as an infectious disease affecting many persons at the same time, more especially during the hot season and in populous districts, where it caused a high mortality among children, he said that the bacteriology of it was far from being settled. Most observers, following Escherich and Hueppe, believed that the bacillus coli communis was the most important factor in its causation, but Finkler and Prior ascribed it to a spirillum, Klein to the bacillus enteritidis sporogenes, Holst to various streptococci, and Baginski to bacillus lactis aërogenes After giving particulars of various outbreaks which he had carefully examined, especially those of milk diarrhœa at Manchester in 1894 and of pork pie and sausage poisoning at Derby in 1902 he said that the general conclusions at which he had arrived were that epidemic diarrhœa was caused by bacteria of the bacillus coli group, the least virulent being those that most resembled the bacillus coli communis of Escherich and the most virulent being those that most closely approximated to the bacillus enteritidis, especially the bacillus enteritidis of Gaertner The most dangerous were consequently those that acidified or coagulated milk or imparted an offensive odour to it and the obvious precautions to be observed were cleanliness, consumption as early as possible refrigeration to 4° C, or sterilisation by heat. Dr Arthur Newsholme opened the discussion and expressed the opinion that while on the one hand milk might be contaminated on the cowkeeper s premises or during transit to the consumer and might in this way give rise to sudden and widespread epidemics, yet, on the other hand, in the numerous sporadic cases which occurred it was *far more probable that it became* contaminated at the home of the consumer, especially among the urban poor The storage of milk and other food in living and sleeping rooms, and the opportunities for its infection by flies which are just come from a privy or other fæcal collections were amply sufficient to account for the prevalence of autumnal diarrhœa and sporadic typhoid fever

THE RECENT INCIDENTS IN THE GRENADIER GUARDS

WE have received several communications concerning what is known as the "Guards Scandal" inviting an opinion on this deplorable matter from a medical point of view The medical bearings of the case seem to us remote but this appears not to be the opinion of some of our readers Firstly it is suggested that the corporal injury inflicted by the illegal tribunals of junior officers might produce some of the terrible results that are known to have followed upon flogging in the army in the olden days In spite of one passage in Admiral Cochrane's shocking letter published in the *Times* on Tuesday last we do not think it at all probable that actual physical harm—harm, that is of the sort that might be serious to health—has ever been done in the course of the extraordinary and degrading ritual practised upon each other by the junior officers of the Grenadier Guards Acute mental suffering resulting, perhaps, in grave impairment of the efficiency of the victims to discharge their duties as officers, may have occurred, and upon such a condition a breakdown in health may have followed, but we do not suppose that any physical injury directly due to violence can be proved to have taken place Secondly, we have been asked to consider the possibility of a perverted sexual impulse playing a part in the disciplinary code of the Grenadier Guards We consider the suggestion a completely ridiculous one, and, were it not that certain so called humanitarians are sure to begin yelling of flagellation and Sadism, we should not mention the matter We do so now only to laugh at it. But the bare fact that such notions can enter educated brains shows that the incidents must now be thoroughly sifted and explained, and that punishment must be meted out with a strong hand to the true offenders, even though innocent persons have to suffer for an evil system or individuals in high posts have to pass out of official life We have lately in our columns discussed certain of the reasons that contribute to the difficulty which our country has in obtaining an efficient army A few more such stories as those that are now rife concerning the Grenadier Guards will leave us with no officers at all Therefore the stories must be made the subject of rigorous scrutiny Students of high education and elaborate training are not likely to enter upon a career where, even while they are successful in the performance of the duties which their country expects from them, they may have to submit to a disgusting penal code, yet these are exactly the kind of men whom recent events show to be the officers that we want. Again, those fortunate youths of rank and position whose desire it has hitherto been to be officers in our cavalry regiments, and whose personal prowess no one who remembers the episodes of our struggle with the Boers can deny, will certainly not desire commissions any longer We regard the situation as a most serious one, calling for an immediate, full, and fearless investigation

EPSOM COLLEGE

His Royal Highness the Prince of Wales has consented to take the chair at the festival dinner to be held this year, at a date shortly to be announced, in aid of the funds of the Royal Medical Benevolent College. The interest taken by the Royal Family in the affairs of Epsom College is thus again manifested, for some 50 years ago the buildings of the College were opened by the Prince Consort, who was accompanied by a little boy his eldest son, our present King

BURIAL GROUND SITES

ALTHOUGH both the testimony of experience and the tendency of certain bacteriological investigations seem to show that the danger to be anticipated from a properly managed graveyard is not so great as was once believed, it is eminently desirable that sites for such places shall be selected with the greatest circumspection. Not only must attention be given to the possibility of the pollution of water supplies whether public or private, but the probability of the insuction of polluted ground air into houses which have not been properly protected against such insuction must be carefully guarded against. Moreover, it cannot be contended that the proximity to an inhabited house of a burial ground which is in actual use is a matter of indifference to the landlord or occupier of such house Although experience may have shown that houses have been built up to the boundaries of existing burial grounds, and that it is difficult to detect any detrimental effect upon the health of the occupiers of such houses, it seems to us that the provisions of the Public Health Interment Act of 1879 which enact that in the absence of the written consent of the owner, lessee, or occupier of a house, no part of a cemetery shall be constructed nearer to such dwelling than 200 yards, should, on the grounds of public health and equity, be duly observed The margin provided for is not a very onerous one and it can hardly be contended that the exigencies of interment are at present so pressing as to call for legislation which shall dispense with this very reasonable provision Certainly, were we the possessors or occupiers of a house and a medical officer of health were to press the establishment of a burial ground within, say, 100 yards of such house, we should do our best to convince the justices that the step would be an illegal one There would seem to be no justification for a sanitary authority, the duty of which it is to see that the Public Health Acts are observed, to attempt, without extremely strong and altogether exceptional reasons, to run counter to such statutes, and certainly the Public Health Interment Act was enacted largely as a public health measure. A sanitary authority which makes light of its obligations may find the public quick to follow the example.

THE Lettsomian Lectures of the Medical Society of London will be delivered by Dr H. Radcliffe Crocker on Feb 16th and March 2nd and 16th, their subject being "The Conditions which modify the Characters of Inflammations of the Skin and their Influence on Treatment." The lectures will commence at 9 P M

THE Lord Mayor and the Lady Mayoress of London will on Monday Feb. 16th at 3 P M , open the 30 additional beds at the Royal London Ophthalmic Hospital towards the maintenance of which a grant has been made by King Edward's Hospital Fund for London.

THE Hunterian Oration of the Royal College of Surgeons of England will be delivered in the theatre of the College on Saturday, Feb. 14th, at 4 P M., by the President, Sir Henry G Howse

---

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms Hotel Métropole, on Saturday, March 7th, at 7 30 P M

THE FIRST REPORT OF THE DEPARTMENTAL COMMITTEE APPOINTED TO INQUIRE INTO THE VENTILATION OF FACTORIES AND WORKSHOPS[1]

THIS report serves to mark a considerable advance in knowledge regarding the practical application of methods of ventilation and describes an apparatus which has been designed for the rapid determination of the amount of carbon dioxide (carbonic acid) which is present in the air These two points are perhaps the most important features of the book, but a very large amount of information on various other important matters is to be found scattered through its pages, and much of this material will be very useful to those who write text books on hygiene and questions concerning the public health generally

The departmental committee responsible for the report was appointed by Sir Matthew White Ridley in July, 1900, when he was Secretary of State for the Home Department. It consists of two members only, Dr John Scott Haldane F.R.S , and Mr E H. Osborn, engineering adviser to the Chief Inspector of Factories The report itself is short, consisting only of three pages and there are three appendices which deal respectively with (1) the results of examinations of ventilation of factories and workshops , (2) the conditions of efficient ventilation , and (3) the method for the quantitative determination of carbonic acid in the air of factories and workshops.

The apparatus which has been devised by Dr. Haldane for the rapid determination of the amount of carbonic acid contained in a specimen of air is fully described and there are three illustrations, two of which were drawn up by Mr Pendock. By its use an analysis may be completed, it is stated in about four minutes and those who have had the practical experience of making such determinations with the apparatus formerly in use will welcome any improvement which may be made It should be added that the new apparatus is not bulky and that it is easily portable. Another instrument has been devised to facilitate the extraction of specimens of air contained in small vessels and illustrations are given of bottles fitted with glass stoppers and provided with elastic bands and labels By means of these appliances it will be easy for factory inspectors to take a number of specimens of air and for the analyst to carry out a large number of analyses in a short time It must be confessed that the amount of air operated on is very small, not more than 25 cubic centimetres, and therefore any slight error of reading would make a great difference when calculated to 10,000 volumes of air And we observe that Dr Haldane obtains decidedly lower results for normal air than are given at any time in the classic researches of Pettenkofer, Risler, Saussure, Angus Smith, Marcet, and others.

The results of examinations of the air of factories and workshops which are given in Appendix I. (pp 7-90) show clearly enough that the present condition of things is by no means satisfactory The experiments recorded were carried out in the case of a vast number of trades, clothing factories, both English and Jewish, tailoring workshops dressmaking and boot workshops, laundries, cabinet and upholstering works, bakeries printing offices and stationery factories, engineering and file cutting factories woollen and cotton mills (humified and non humified) Some of the places examined are briefly described in the tables which are given, and it is not unworthy of note that some of the worst are in the rural parts of England. This point cannot be dwelt upon and a single example must suffice. A boot workshop in Gloucestershire was found to be ' a stuffy little place with less than the statutory (minimum of) 250 feet per person. Dark, dingy, and wretched, smell of oil, rough earth floor, very dirty, air stagnant and obviously foul." Analysis of the air showed that it contained 23 4 volumes of carbonic acid per 10,000, the corresponding amount in the outside air being 3 0

The account given of the conditions necessary for efficient ventilation (Appendix II., pp 93-144) is of extreme value. It commences by recording analyses of air in towns and in the country and then deals in detail with the nature of the impurities contained in the air of factories and of workshops, impurities from persons, from "lights" from dust and from fumes, and particulate matter given off in special processes of manufacture. The influence of the various impurities on the composition of the air is considered in detail. For purposes of description ventilation is divided into (1) natural ventilation, (*a*) without special openings, (*b*) through special openings , and (2) ventilation by fans The information on the latter subject, which is clearly and concisely given, will prove of great service to manufacturers who have at heart the good of their workpeople. The more general use of fans in large factories is greatly on the increase, and in cases in which large numbers of people are present in a small space their use is now universally appreciated The advantages of the method—which are, briefly that a practically unlimited amount of air can be introduced, that the supply is under control, that the incoming air can be warmed, moistened, or filtered should occasion require—are fortunately becoming matters of common knowledge. There is, however one fact established in the report which has hitherto not obtained the attention which it deserves It has of course been generally known that ventilation is carried out in no small measure through the walls of buildings, but the fact that a very large proportion of the fresh air is introduced in this way is by no means a fact which is fully appreciated Its importance is great and we have often insisted on this subject, especially when dealing with experiments on ventilation made on the continent and the teaching of that eminent architect and sanitary reformer M. Emile Trélat. It makes it at once evident why a detached house has the advantage of a semi detached house and why the end house of a row is better than one which has houses on each side. These things have been long recognised by the observant, although the reason of them was not generally understood The results of a series of experiments on the introduction of air through the wall of a room are given in the report and the information derived from them may come as a surprise to many people. It is hardly necessary to say that too much importance should not be given to a single series of experiments and the subject is certainly worthy of further investigation under varying conditions For example, the nature and thickness of the walls of the room the solidity or hollowness of the walls, the presence or absence of paper and of paint and the composition of the paper—all these things will undoubtedly be found to affect the result.

The recommendations given to the Secretary of State by the departmental committee are five in number and are as follows —

1 That the Secretary of State should prescribe for all classes of factories and workshops not otherwise specially dealt with that the proportion of carbonic acid in the air at about the breathing level and away from the immediate influence of any special source of contamination, such as a person or light shall not (except on very foggy days when no tests should be made on account of the vitiated state of

---

[1] London, 1902 (Cd 1302) Eyre and Spottiswoode

the outside air) rise during daylight or after dark when only electric light is used beyond 12 volumes of carbonic acid per 10 000 of air and that when gas or oil is used for lighting the proportion shall not exceed 20 volumes after dark or before the first hour after daylight the only exception to this rule to be in cases where the extra carbonic acid is produced in other ways than by respiration or combustion as in breweries &c.

2. That in the case of cotton cloth factories with artificially humidified air the occupier should have the option of coming under the regulation just mentioned instead of remaining under the existing regulation

3 That inspectors of factories should inform employers of the results of any official analyses of the air in their factories or workshops should give notice that the ventilation is deficient to any employer in whose factory or workshop the above proportions have been found to be exceeded and at the same time supply so far as practicable information as to the nature of any defect noticed and that legal proceedings should not be taken against an employer unless after a reasonable interval following such notice, the stated proportion is found on an average of two or more samples taken in different parts of the room to be again exceeded by one volume or more and he is unable to show that he has taken measures reasonably calculated to secure the requisite ventilation

4 That arrangements be made by the factory department of the Home Office for the analysis by a specially qualified person or persons of samples of air collected by inspectors (see Appendix III) and that any analysis on which a prosecution immediately depends shall have been performed by such qualified person or persons.

5 That arrangements be made for inspectors of factories to have the use when desired of a properly tested portable apparatus for estimating on the spot the proportion of carbonic acid in air

It may be seen from what has been said that the report deserves careful consideration. In regard to the recommendations which are given *in extenso* it must suffice to say that the first is open to very grave objection , the last two, it will be seen, are devoted to recommending the general use of Dr Haldane's apparatus

PUBLIC HEALTH IN BOMBAY

IN his annual report for the year 1901[1] Dr J A. Turner executive health officer of the city of Bombay, gives much information highly valuable from the point of view of urban sanitation and public health. A report in which he dealt with the occurrences of the first quarter of 1901 was published a considerable time ago and was reviewed at some length in THE LANCET of Sept. 14th, 1901, p 746, chiefly with reference to proposals which he had made for an improved sanitary administration of the city The present report with its statistical appendices consists of 96 closely printed pages and is illustrated with four coloured diagrams. Bombay is built on an island which has an area of about 22 square miles and part of which is below the level of high water mark, so that drainage presents considerable difficulties Increase in sickness during, and immediately after, the rains, which occur in June July, and August, is chiefly due to the dampness of the soil and moisture of the atmosphere. In most of the houses of the poorer classes the floors are of mud and cowdung and the people sleep on the ground. The cold weather season, extending from December to March, is the period of highest mortality, the hot weather from March to June the lowest, and from June to November the period of seasonal increase in the mortality In the cold weather when the people are obliged to sleep indoors, over crowded and in a vitiated atmosphere, plague spreads rapidly, while the cold air easily affects them when exposed to it, causing diseases of the respiratory system The population according to the census of 1901 was 776 006, the proportion of males to females being 161 9 to 100 The principal divisions of the population were as follows Hindus, 522,947 , Mussulmans, 155,121 , Parsees, 46,231 , Jews, 5357 , Native Christians, 29,645 , Eurasians, 3258 , and Europeans, 12,273.

The number of births registered during the year was 13,520, giving a birth rate of 17 42 per 1000 The number of deaths during the year exclusive of stillborn, was 59,495, giving a death rate of 76 6 per 1000 Of late years the death rate has fluctuated considerably and has increased very much since plague acquired a footing in the city Thus the rates per 1000 were 29 0 in 1891, 30 5 in 1895 58 3 in 1897, 63 2 in 1898, 68 1 in 1899, 96 5 in 1900, and 76 6 in 1901. The number of deaths from zymotic diseases was 30,593 giving a zymotic death rate of 39·4 per 1000 The detailed list shows that 18,736 deaths were due to plague, 7266 to remittent fever, 1560 to relapsing fever, 1341 to dysentery, 514 to puerperal fever, and 198 to cholera. The total deaths among Europeans were 189, the detailed list showing that of these 18 were due to enteric fever, 14 to ague and remittent fever, 10 to plague, 29 to diseases of the nervous and circulatory system, 20 to diseases of the respiratory system, and 46 to diseases of the digestive system. The deaths are also classified according to the occupation of the deceased—whether engaged in, or belonging to, the service of the imperial, local, or municipal governments, the army or navy, the learned professions, domestic work, commerce, agriculture, and so on , for some unexplained reason one of the nine sub headings under "learned professions" specifically includes dancers, jugglers, snake-charmers, and billiard room keepers.

During the greater part of the year the control of all plague measures was under the Government, as in the previous year, but in October Dr Turner took over the duties of supervision in addition to his own and the control of plague is now in the hands of the Health Department The mortality from this disease began its seasonal rise in December, 1900, reached its maximum in February, 1901, and then declined There were 21,006 attacks and 18,736 deaths from plague during the year, as against 17,913 attacks and 13,285 deaths during the previous year, and the increase was felt in all the communities except the Europeans, among whom there were only 10 deaths, as against 11 in the previous year The mortality from plague was highest on Feb 26th, when 214 deaths were registered. The measures adopted for controlling the disease were the provision of camps for those willing to evacuate plague stricken houses, disinfection by washing the rooms with perchloride of mercury and phenol, and fumigation with sulphur Compulsory removal to hospital was not practised. The disease was of a very virulent type, the mortality in hospitals varying from 79 to 91 per cent The preparation of Lustig's anti plague serum was continued throughout the year at the municipal laboratory and patients at the Arthur road Hospital were treated with it

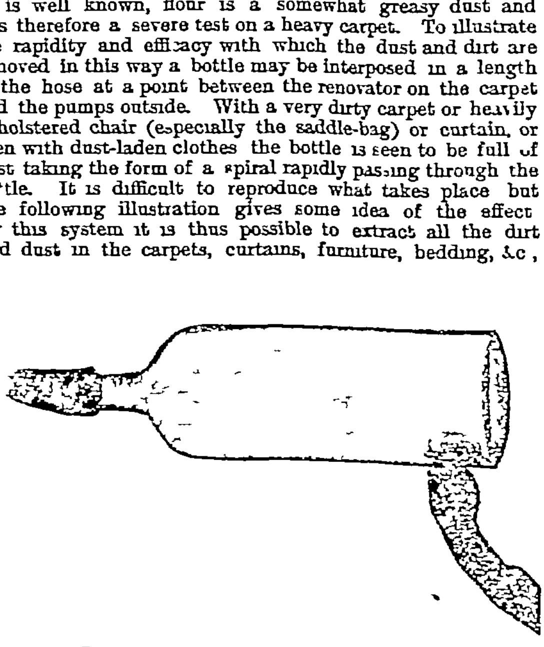
Dr Turner devotes several pages to an enumeration of the defects existing in the sewerage system of the city and in the methods of dealing with excrement and refuse. He also makes a variety of suggestions for their improvement. On the subject of the administration of the Health Department he says that during the past three years the investigation into the cause and control of all epidemics of infectious disease has not been vested in the Health Department, and that a health officer's ardour must be damped when his more important and interesting work is transferred to others unqualified in any way for the position. The work of the Health Department has, however, now reverted to its proper channel. During the year he was called upon to submit a report on the reorganisation of the department, and his report was directed chiefly towards—(1) an improved sanitary inspection , (2) a better class of inspectors , (3) a better system of refuse removal , (4) a more complete system of registration of births and deaths and notification of infectious diseases , (5) inspection of food, drugs, and milk supply , (6) a laboratory for analysis of food and drugs and chemical and bacteriological examination of water and pathological products , (7) a municipal analyst , and (8) ten municipal dispensaries. Progress has been made in the carrying out of these recommendations Of the other points in which improvement is required the chief are (1) hospital accommodation , (2) medical relief , (3) house drainage , (4) housing of the poor and over crowding , and (5) control of milch cattle stables by the Health Department with registration of all cow keepers and milk sellers The Arthur road Hospital is at present the only accommodation provided by the municipality for cases of infectious disease other than plague and the expenditure on it is relatively small, being only Rs.40,000, or £2660, per annum Dr Turner recommends that the accommodation should be increased and made sufficient for the reception of 100 patients In order to counteract the prejudices which the poorer classes have against hospital treatment he proposes to issue a circular inviting them to visit Arthur road Hospital so that they may see for themselves how well the sick are treated. We presume that these visitors would be admitted only to the parts of the institution occupied by convalescents fit for discharge. The highest mean monthly shade temperature recorded at Bombay Observatory was 86 6° F for May The total rainfall was 75 32 inches, of which 72 33 inches fell in June, July, and August.

---

[1] The issue of this report is not so belated as might be inferred from the fact that it only reached us about a fortnight ago, Much time is sometimes taken up in the preparation of such documents for publication and in submitting them to various official departments. Moreover the statistical returns of patients admitted into the Arthur road Hospital are brought down to May 1902.

CLEANING BY VACUUM

THERE are few surely who are not averse to the ordinary annual house-cleaning process commonly called ' spring cleaning," at any rate during its progress, however pleasant and comfortable the results may be. "Spring cleaning,' in fact, entirely disturbs the routine of a household and the occupant, unless he is lucky enough to be able to go away during the process, is put to manifold kinds of inconvenience and discomfort. Therefore a process by which it is proposed to reduce this inconvenience to practically *nil* whilst the work of cleaning is done effectively is certain to be welcomed by a very large section of the community But the vacuum cleaning process deserves attention not on account of its being expeditious only but because it removes dust, and therefore septic matter in such a way as to render their complete destruction ultimately possible The process is simple enough and, indeed, such that it is a little astonishing that it has not been suggested and applied before. When spring cleaning is to be done a machine is sent to the house provided with a pair of vacuum pumps actuated by an oil or electric motor which serve to maintain an "exhaust ' of several pounds to the square inch. Varying lengths of hose are connected with this exhaust' and terminate in so-called "cleaners" or "renovators" which consist of tubes flattened out at the end into a kind of long slit. The renovator" is rubbed up and down the carpet or the cloth coverings of seats or chairs from which it rapidly sucks out all the dust. The result is quite remarkable. The dust is extracted not only from the surface but from the body of the carpet also so that at the end of the process not the slightest cloud of dust can be detected on beating the material. On sprinkling the carpet with flour, rubbing it well in so that it disappears to view, the vacuum renovator will be found to remove every particle As is well known, flour is a somewhat greasy dust and it is therefore a severe test on a heavy carpet. To illustrate the rapidity and efficacy with which the dust and dirt are removed in this way a bottle may be interposed in a length of the hose at a point between the renovator on the carpet and the pumps outside. With a very dirty carpet or heavily upholstered chair (especially the saddle-bag) or curtain, or even with dust-laden clothes the bottle is seen to be full of dust taking the form of a spiral rapidly passing through the bottle. It is difficult to reproduce what takes place but the following illustration gives some idea of the effect By this system it is thus possible to extract all the dirt and dust in the carpets, curtains, furniture, bedding, &c , *in situ* Carpets need not be taken up and need not be sent away, or curtains, furniture, or bedding and the whole operation in a 10-roomed house need not occupy more than eight hours, the time taken depending upon the amount of dirt it is possible to remove and upon the nature of the furniture



Bottle during the application of the renovator"

It is remarkable, as it is important from a sanitary point of view, that during this process dust or dirt is not raised in the room, for exhaustion is proceeding the whole time, the air of the room is constantly being changed, and it will be found when the cleaning process is over that the shelves, the mantelpiece, or the cover of the piano will be free from all signs of deposited dust This result alone constitutes a great advance on other methods which at their best remove the dust from one place only to scatter it in another Such, at any rate, is largely the result of sweeping Far from producing any deteriorating effect upon the carpet it improves it by restoring the pile and its colour. The restoration of the colour, especially of a dirty oriental carpet, is very marked and is seen the moment the renovator is applied. In a similar way the dust may be removed from the walls by means of a special cleaner which consists of a brush of horse shoe shape provided with an exhaust tube in the centre. The dust and dirt rapidly travel along the hose to the exhaust cylinder of the machine where they are deposited upon a screen.

An idea of the amount of dust which this method is capable of removing will be gained from the following results of its application to certain of the theatres and hotels of London. The carpets, curtains, and upholstery of the Royal Camden Theatre yielded no less than 408 pounds of dust by this method , similarly the Kennington Theatre yielded 382 pounds and the Coronet Theatre, Notting hill gate, 300 pounds, the Midland Hotel, St. Pancras, 196 pounds, the Savoy Theatre 82½ pounds, the coffee room and smoking room of the Junior Army and Navy Club and smoking room carpet 68 pounds, a restaurant carpet from the Carlton Hotel 46 pounds, a railway-carriage on the London and North Western Railway 4¼ pounds, the tea room and corridors of the House of Commons 25 pounds, and so on. We have seen the process at work in a music hall and in a private dwelling house and in both cases the results were very striking and the demonstration was very satisfactory The value of this method from a sanitary point of view is self evident, for the dust is entirely removed without scattering and is then collected for subsequent incineration. According to Mr Stanley Kent of the Clinical and Bacteriological Research Laboratory University College Bristol, the following organisms were isolated from a specimen of dust removed by this process—proteus vulgaris and other forms of proteus, bacillus subtilis, streptococcus (several forms), staphylococcus pyogenes aureus, staphylococcus pyogenes albus, diplococcus (several forms) sarcina flava, micrococcus tetragenus, micrococcus prodigiosus and the following moulds mucor mucedo, penicillium glaucum, and a red yeast. A sample of house dust removed by this process and taken by ourselves at a demonstration gave the following results on analysis organic matter 35 30 per cent. , moisture, 5 30 per cent. , and mineral matter, 59 40 per cent. Under the microscope starch cells, human hair, cotton fibre, &c , were easily detected. The mineral matter contained common salt potassium carbonate with some lithium carbonate (probably from tobacco ash), sand, clay, silica, alumina, and iron. The process is not costly considering the thorough way in which the work of cleaning is done and having regard to the inconvenience which it avoids and the expense which it saves, due, under existing methods, to removing carpets and replacing them, picking mattresses to pieces, and so forth The satisfactory removal of dust and dirt from the interior of a house has long been a troublesome matter, though sanitation demands that it should be regularly done, and this process it seems to us deals with it in a much more scientific way than has hitherto been possible. This method of cleaning by vacuum is being developed by the Vacuum Cleaning Co , Limited, of 25 Victoria street, Westminster, London, S.W

ASYLUM REPORTS

London County Asylum Hanwell (Report for the year ended 31st March 1902)—The average number of patients resident during the year was 2537 comprising 957 males and 1580 females The admissions during the year amounted to 480—viz 297 males and 183 females Of these 396 were first admissions Dr R. R Alexander, the medical superintendent, states in his report that 19 per cent of the male admissions and 4 per cent. of the female were cases of general paralysis. As the result of careful inquiry into the histories of patients it appeared that about 80 per cent. of the general paralytics had had syphilis As to the causes of the mental disorders among the patients admitted alcoholic intemperance was found in 32 per cent. of the males and 16 per cent. of the females The corresponding figures for males were 15 per cent. in 1898, 20 per cent. in 1899, and 25 per cent. in 1900, and for females the figures were 8, 12, and 13 per cent respectively Dr Alexander emphasises the "increasing share alcohol has directly or indirectly in the production of insanity, especially in the case of the men," and adds that if due allowance were made for the wilful concealment of a history of intemperance by relatives and friends of the patient the etiological frequency of alcoholism would be higher than the above. A hereditary predisposition to insanity was ascertained in 18 per cent of the males and 30 per cent of the females The number of patients discharged as recovered during the year amounted to 163—viz, 79 males and 84 females, or 6 4 per cent of the average number resident The deaths during the year amounted to 212—viz., 119 males and 93 females—or 8 3 per cent as calculated on the same basis Of the deaths, five were due to renal disease, seven to colitis, 12 to epilepsy, 13 to inflammation of the lungs, 19 to cardiac disease, 20 to senile decay, 21 to pulmonary and other forms of tuberculosis, 62 to general paralysis of the insane, and the rest to other causes The general health of the institution had been good There had been two cases of enteric fever and two small outbreaks of dysentery The latter could not be traced to overcrowding or any other sanitary defect. "Judging by its high infectivity, its tenacious hold on a ward, its stubborn resistance to treatment, its heavy mortality in the broken down, and its marked tendency to recur without any abatement of its original infectivity, I am disposed to believe that our dysentery of recent years is of a different variety from the sporadic dysentery that occasionally figured in our sick and death returns prior to 1895" There were no serious casualties in the institution during the year A male patient while out on trial made a murderous attack on his wife, who ultimately recovered, though for a time her life was despaired of During the epidemic of small pox in London all precautions, including vaccination of patients and restriction of visits from relatives, were adopted and the results were quite satisfactory The Commissioners in Lunacy state in their report that the asylum continued to be maintained in very good order, that the dormitories and bedding were scrupulously clean, that the patients were neatly dressed and orderly in habits, and that the medical case books were well kept. The committee of management states in its report that alterations and improvements according to a scheme approved by the London County Council in 1894 were completed, the net expenditure having amounted to £66,840 The expenditure on ordinary repairs and alterations during the year was £7689

London County Asylum, Bexley heath (*Report for the year ended March 31st, 1902*) —The average number of patients resident during the year was 1893, comprising 942 males and 951 females. The admissions during the year amounted to 1175, including 502 males and 673 females. Of these 1145 were first admissions. Dr T E. K Stansfield, the medical superintendent, states in his report that the year has been one of great pressure and "the asylum is now fully occupied. The villas which constitute one of the leading features of this asylum have now been in occupation under sufficiently varying conditions of season, weather, and temperature to justify one in giving a definite opinion as to the value of this system of housing a large proportion of the insane, as compared with the most recent 'barrack' system typified in the other part of the asylum, and I have no hesitation in pronouncing in the strongest terms in favour of the former" The number of cases among the admissions suffering from advanced age and physical decrepitude was unusually large, 206 patients, or 17 5 per cent, being over 60 years of age Pediculosis to a greater or less extent existed in 23 per cent of the admissions Evidences of syphilis were made out in 131 cases, or 30 per cent., among the males, and in 61, or 19 per cent, of the females. "The form of insanity most frequently associated with syphilis is general paralysis. 79 males and 20 females were admitted suffering with this disease (general paralysis) and of these 59 males (74 6 per cent.) and 11 females (55 per cent.) had undoubted evidence of syphilis." Alcoholic intemperance was present in 181 of the admissions, comprising 130 males (30 7 per cent.) and 51 females (16 per cent.), the form of intemperance being heavy drinking or secret "tippling" in small quantities for many years The number of patients discharged as recovered during the year amounted to 202—viz., 98 males and 104 females—or 9 5 per cent of the average number resident. The deaths during the year amounted to 281, including 157 males and 124 females, or 14 8 per cent, as calculated on the same basis. Of the deaths six were due to epilepsy, nine to bronchitis, 10 to renal disease, 15 to colitis, 21 to pneumonia, 27 to phthisis and other forms of tuberculosis, 32 to cardiac disease, 89 to general paralysis of the insane, and the rest to other causes The general health of the institution has been good, with the exception of colitis, "which disease has, I fear," adds Dr Stansfield, "become endemic here." Influenza was prevalent in January and February The well has yielded a constant supply of excellent water and the farm crops are reported as particularly good The Commissioners in Lunacy state in their report that the patients were orderly, neat, and tidy, that the dormitories and day rooms were in very good condition, and that the medical case-books were admirably kept The committee of management states in its report that the whole institution is fitted with telephones and fire alarms and lighted with electricity The expenditure on alterations, repairs, and improvements amounted to £4606 during the year

Montrose Royal Asylum (*Report for the year ended May 14th, 1902*) —The average number of patients resident during the year was 690, comprising 317 males and 373 females The admissions during the year amounted to 189—viz., 86 males and 103 females Of these 152 were first admissions. Dr John G Havelock, the medical superintendent, states in his report that a large number of the patients who were admitted were "in very frail bodily health, some in the last stages of incurable disease and many others in a state of senile decay with the vital functions rapidly wearing out" There seems to be an increasing tendency in the poorer classes, adds Dr Havelock, to send such cases to an asylum rather than to attempt to manage them in their own homes until the end comes, with the result that asylum accommodation is taxed to its utmost The prejudice against asylums is gradually disappearing under the influence of modern methods of asylum management and the custom of sending to asylums idiots half witted youths, disorderly inebriates, restless dotards, and persons who are the victims of drug habits is on the increase, and causes the appearance of a rapid growth in lunacy among the population The number of patients discharged as recovered during the year amounted to 74, or 10 7 per cent. of the average number resident. The deaths during the year amounted to 95—viz., 35 males and 60 females, or 13 7 per cent. as calculated on the same basis Of the deaths three were due to epilepsy, four to cardiac disease, six to cancer, eight to pulmonary and other forms of tuberculosis, nine to exhaustion from mania and melancholia, 14 to lobar pneumonia, 15 to general paralysis of the insane, 24 to senile decay, and the rest to other causes "An outbreak of influenza in the winter months was followed by various complications which carried off a number of feeble senile patients, causing the death rate to be higher than the average of recent years" The erection of a new villa for female patients has been started and it is hoped to complete the building during the year 1903 The whole of the institution is now furnished with electric lights. The Commissioners in Lunacy state in their reports that the general condition of the patients was highly satisfactory, that the dietary was adequate and judiciously arranged that the wards and rooms were in excellent order and that the medical case-books and registers were carefully and correctly kept The committee of management states in its report that the profit on the farm and garden account was £414 during the year, that a system of telephones has been fitted throughout the building that a villa for male patients has been completed and is now occupied, and that the villa for female patients will be completed in a short time

MEDICINE AND THE LAW

Injury by Nervous Shock

IN an action tried before Mr Justice Bigham at the Devon assizes the plaintiffs, a husband and wife, were tenants of a house and the defendants were making excavations at an adjoining site This they did with the result that the house occupied by the plaintiffs after showing signs of subsidence, fell in ruins. The female plaintiff, finding that her home was apparently threatened with destruction, hurried out to a relative near by to ask what she should do leaving her children behind her As she was returning the actual collapse took place with the result that, knowing that her children might be buried in the ruins, she sustained a very severe fright and shock with consequent injury to her health. The children had, as a matter of fact, been removed to a place of comparative safety and had not suffered. After a legal argument the judge left the following questions to the jury whether the shock sustained by the plaintiff was due (1) to fear for her own personal safety, or (2) to fear for the safety of her children, or (3) to fear for the safety of herself and her children The jury found that it was due to the last of these alternative causes, and in reply to a further question also found that the shock had produced personal injury Upon this the judge directed them that the plaintiff was not entitled to damages in respect of the shock caused by fear for the safety of her children, but that they might be awarded to her in respect to the shock caused by fear for her personal safety, and he told them to apportion the damages accordingly with the result that the plaintiffs obtained a verdict for £250 The question of liability for fright resulting in nervous shock and actual injury to health is a more or less open one in the eye of the law The Privy Council has held in a case that came from the colonies that an action will not lie for negligence where the damages arise from mere sudden terror occasioning a nervous or mental shock, but unaccompanied by any physical injury on the ground that injury to health in such circumstances cannot be considered as a natural consequence of the negligence. This decision was given where a woman, who had had a hair's breadth escape from being run over by a train at a level crossing through the negligence of the defendant railway company's servant had a miscarriage and otherwise suffered severely in her health as the result of her fright. It has however, not always been followed, and in Ireland it has been apparently considered and disregarded by the Exchequer Division, as well as upon other occasions and there is a recent judgment of Mr Justice Wright in an English case in which the question of injury by terror was gone into upon slightly different facts. In this instance a man was held liable who had made a woman ill by giving her fictitious bad news of her husband by way of a 'practical joke" Legal questions must always interest medical men in cases with regard to which medical evidence is of paramount importance so far as the facts are concerned. When once the principle is established from a legal point of view that injury to health may be the natural consequence of an act of negligence without any physical impact of anything injurious taking place the question of whether the injury was in fact due to the act alleged must in each case be one for medical evidence only Mr Justice Bigham's direction to the jury at Exeter is no doubt likely to come under review in London later It will be seen that it involves a little more than previous judgments by establishing a distinction between the fright of the plaintiff on her own account and her fear for her children. The jury seem to have been equal to the occasion and to have decided questions upon which only a jury would be asked to adjudicate. They cannot have derived much assistance from medical witnesses in determining the exact proportion of the plaintiff's ill health which was caused by her fear for herself as distinct from her fear for her children and in assessing the damages upon that basis

The Drink Question

Reference was made in THE LANCET of Feb 7th at page 331 to the letter of a Great Yarmouth magistrate to the *Times* calling attention to the unusually large number of licensed houses in that town in proportion to the number *of its inhabitants.* In case any who read the note in question may have wondered how public houses contrive to pay their way where they have so many competitors it will be instructive to quote from the *Western Morning News* of Feb 7th some of the evidence given before the borough bench at Exeter in opposition to the renewal of the licence of a "hotel there. The witness was a soldier recently returned from South Africa. He said that he came home from the front on August 6th. On Coronation Day (August 9th) he received £5 from the depot and went to the Blackamoor's Head, where he cashed the cheque and had a drink. He then went to the Albion and remained there from about 8 30 in the morning until 9 or 10 o clock in the night and went home penniless. He must have thrown or given away a lot of his money About a fortnight afterwards he received £30 from the Government It lasted about a week and most of it was spent at the Albion." In cross examination he stated further that "since he had been home he had received as much as from £60 to £70 from the depot. He had two months sick furlough and was drunk nearly the whole of the time He had never been summoned for drunkenness ' He is perhaps an extreme instance, and the means put suddenly at his disposal were unusually large, but if men of the working-class, when enabled to do so, are ready to ruin themselves in health and pocket like this young fool upon "sick furlough" it cannot be a matter of surprise that a large amount of disease want, and crime should be attributable to the abundant temptations put in the way of the weak and self indulgent It is also only to be expected that fresh applicants for licences should always be forthcoming wherever there is any population likely to supply them with customers.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9220 births and 5164 deaths were registered during the week ending Feb 7th The annual rate of mortality in these towns which had been 17 5, 20 1, and 18 1 per 1000 in the three preceding weeks, further declined to 17 9 per 1000 last week In London the death rate was 17 6 per 1000, while it averaged 18 0 in the 75 other large towns. The lowest death rates in these towns were 7 4 in Bournemouth 8 0 in East Ham 9 8 in York, 11 1 in Willesden, 11 3 in Hornsey, 11 9 in Grimsby, 12 0 in Devonport, 12 2 in Halifax, and 12 4 in Barrow in Furness, the highest rates were 22 3 in Bootle, 22 4 in Bury 22 5 in Bradford 23 0 in Newcastle-on Tyne, 23 3 in Liverpool, 23 5 in Wigan, 24 2 in Preston, 24 8 in Tynemouth, and 31 3 in Hanley The 5164 deaths in these towns last week included 512 which were referred to the principal infectious diseases, against 450, 539, and 493 in the three preceding weeks, of these 512 deaths 162 resulted from whooping-cough, 92 from measles, 88 from diphtheria, 70 from diarrhœa, 51 from scarlet fever, 35 from 'fever' (principally enteric) and 14 from small pox. No death from any of these diseases was registered last week in Portsmouth, Bournemouth, West Bromwich, Wallasey, Barrow in Furness, Halifax, York, or Stockton on-Tees, while the highest death rates from the principal infectious diseases were recorded in Tottenham, Great Yarmouth, Hanley, King's Norton, Wigan, Salford, Rotherham Hull, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Wigan, Manchester Salford Newport (Mon.), and Merthyr Tydfil, from scarlet fever in St Helens and Wigan, from diphtheria in Hanley Coventry, and Salford, from whooping-cough in Croydon Tottenham, Great Yarmouth, Hanley, Grimsby Stockport Preston, Rotherham, Tynemouth, and Merthyr Tydfil from fever in Rochdale, and from diarrhœa in Walsall. 14 deaths from small pox were registered in the 76 towns last week, of which seven occurred in Liverpool and one each in Birmingham, Bootle, Bolton, Leeds, Sheffield, Rotherham, and Hull The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had been five four and seven at the end of the three preceding weeks, had declined again to six at the end of last week, four new cases were admitted during the week, against two, none, and six in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday Feb 7th was 1941, against numbers decreasing from 2528 to 2017 on the six preceding Saturdays, 189 new cases were admitted last week, against 193, 227 and 227 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had been 310 411 and 355 in the three preceding weeks, further declined last week to 315 and were 93 below the corrected average number The deaths in London directly attributed to influenza numbered 39 last week, against 34 43 and 25 in the three preceding weeks The causes of 60, or 1 2 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Leicester, Manchester, Leeds, Newcastle on Tyne and in 41 other smaller towns, the largest proportions of uncertified deaths were registered in West Bromwich Birmingham, Liverpool, St Helens, Bury, Sheffield, Stockton on Tees, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 23 4, 24 6, and 21 3 per 1000 in the three preceding weeks, rose again to 21 7 per 1000 during the week ending Feb 7th, and was 3 8 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 13 9 in Perth and 18 2 in Dundee to 24 8 in Leith and 27 0 in Greenock The 711 deaths in these towns included 28 which resulted from whooping cough, 19 from diarrhœa, 16 from measles, seven from diphtheria, six from "fever," four from scarlet fever, and not one from small-pox. In all 80 deaths resulted from these principal infectious diseases last week, against 102 and 81 in the two preceding weeks. These 80 deaths were equal to an annual rate of 2 5 per 1000, which was 0 7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping-cough, which had been 52 and 32 in the two preceding weeks, further declined last week to 28, of which 22 were registered in Glasgow, two in Dundee, and two in Leith The deaths from diarrhœa, which had been 21 and 13 in the two preceding weeks, rose again to 19 last week, and included six in Glasgow, five in Dundee, three in Aberdeen, two in Edinburgh, and two in Greenock. The fatal cases of measles, which had been 11 and 20 in the two preceding weeks, declined again last week to 16, of which nine occurred in Aberdeen, three in Leith, two in Glasgow, and two in Edinburgh. The deaths from diphtheria, which had been six, five, and seven in the three preceding weeks, were again seven last week and were all registered in Glasgow The fatal cases of "fever," which had been eight and five in the two preceding weeks, rose again last week to six, of which five occurred in Glasgow The deaths from scarlet fever, which had been five, five, and four in the three preceding weeks were again four last week, and included three in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 183 and 173 in the two preceding weeks, further declined last week to 134, and were 39 below the number in the corresponding period of last year The causes of 21, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 30 0, 28 1, and 24 8 per 1000 in the three preceding weeks, rose again to 26 4 per 1000 during the week ending Feb 7th During the past four weeks the death rate has averaged 27 3 per 1000, the rates during the same period being 18 4 in London and 18 9 in Edinburgh. The 192 deaths of persons belonging to Dublin were 12 in excess of the number in the preceding week, and included nine which were referred to the principal infectious diseases, against 10 in each of the two preceding weeks, of these, three resulted from diphtheria, three from whooping cough, two from scarlet fever, one from diarrhœa, and not one from small pox, from measles, or from "fever" These nine deaths were equal to an annual rate of 1 2 per 1000, the death rates last week from the principal infectious diseases being 1 9 in London and 0 8 in Edinburgh The deaths from diphtheria, which had been four, three, and one in the three preceding weeks, rose again last week to three The fatal cases of whooping cough also numbered three last week, none having been recorded in either of the two preceding weeks The deaths from scarlet fever which had been two and three in the two preceding weeks, declined again to two last week. Only one fatal case of diarrhœa occurred last week, against six in the preceding week. The 192 deaths in Dublin last week included 40 of children under one year of age and 56 of persons aged 60 years and upwards, these numbers were respectively 13 and six in excess of those recorded in the preceding week Seven inquest cases and two deaths from violence were registered, and 67, or more than a third, of the deaths occurred in public institutions The causes of 10, or more than 5 per cent., of the deaths in Dublin last week were not certified.

Vital Statistics of London during 1902.

Complete statistics relating to sickness and mortality during the year 1902 in the City of London and in each of the metropolitan boroughs are summarised in the accompanying table. The mortality figures relate to the deaths of persons actually belonging to the various metropolitan boroughs, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various boroughs in which the deceased persons had previously resided. With regard to the notified cases of infectious diseases in London during last year it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 9 9 per 1000 of the population, estimated at 4,579 110 in the middle of last year In the three preceding years the rates had been 9 3, 7 7, and 8 9 per 1000 respectively Among the various metropolitan boroughs the lowest rates were 5 3 in Kensington, 5 7 in Hampstead, 6 4 in Paddington and in Chelsea, 6 9 in the City of London, and 7 0 in Hammersmith, the highest rates were 11 3 in Holborn, 11 4 in Hackney and in Deptford, 12 0 in St. Pancras, 12 7 in Stepney, 13 0 in Southwark, and 13 4 in Bethnal Green The prevalence of small pox last year was greatly in excess of that recorded in any other recent year, the number of new cases notified during the year was 7798 against 29, 88, and 1702 in the three preceding years. This disease was proportionally most prevalent in Holborn, Shoreditch, Bethnal Green, Stepney, and Poplar The number of small pox patients admitted into the Metropolitan Asylums hospitals during last year was 8455, against 1788 in the preceding year, only 14 remained under treatment at the end of the year, against 666 at the end of 1901. The prevalence of scarlet fever during the year under notice showed a slight diminution as compared with the preceding year, the number of new cases notified being 18 258, against 18,094, 13,809, and 18,390 in the three preceding years Among the various metropolitan boroughs scarlet fever was proportionally most prevalent in Southwark, Battersea, Camberwell, Deptford, Greenwich, and Lewisham During last year 15 133 scarlet fever patients were admitted into the Metropolitan Asylums hospitals, against 13 641, 10,734, and 14,959 in the three preceding years, the number of cases remaining under treatment, which had been 2797 2460, and 3080 at the end of the three preceding years, had declined again to 2327 at the end of last year The prevalence of diphtheria during last year showed a marked decrease from that recorded in the preceding year, 10,735 new cases being notified, against 12,154 in 1901. The greatest proportional prevalence of this disease occurred in Fulham, St. Pancras, Hackney, the City of London, Wandsworth, and Lewisham The Metropolitan Asylums hospitals contained 927 diphtheria patients at the end of last year, against 1343 and 1369 at the end of the two preceding years, the number of new cases admitted, which had been 8777 and 9090 in the two preceding years, declined again last year to 7988 Enteric fever showed a slightly increased prevalence last year, the number of cases notified being 3412, against 3195 in the preceding year, among the various metropolitan boroughs this disease was proportionally most prevalent in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey The number of enteric fever patients admitted into the Metropolitan Asylums hospitals during 1902 was 1806, against 1835, 2074, and 1480 in the three preceding years, 210 cases remained under treatment at the end of last year, against 406 403, and 195 at the end of the three preceding years Erysipelas was somewhat more prevalent last year than in the preceding year, the highest proportional prevalence of this disease was recorded in St. Marylebone, Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Southwark. The 312 cases of puerperal fever notified during the year showed an excess of 61 over the number recorded in 1901, of these 312 cases 22 belonged to Stepney, 21 to Wandsworth, 19 to Islington, 17 to Hackney 17 to Lambeth, 15 to Kensington, 15 to Battersea, and 15 to Camberwell.

During the year under notice the deaths of 80,105 persons belonging to London were registered equal to an annual rate of 17 2 per 1000, against 19 5, 18 6, and 17 1 per 1000 in the three years, the average rate in the 10 years 1892–1901 was 18 8 per 1000 In the various metropolitan

* Including membranous croup

boroughs the lowest death rates last year were 10 8 in Hampstead, 13 4 in Stoke Newington, 13 5 in Wandsworth, 13 6 in Lewisham, 14 6 in Paddington, and 15 0 in Hackney and in Battersea, and the highest rates were 20 6 in Stepney, 20 7 in Shoreditch, 20 8 in Bethnal Green and in Bermondsey, 21 3 in Holborn, 21 4 in Southwark, and 22 9 in Finsbury Taking the five groups of boroughs the rates of mortality were 16 0 in the West, 16 2 in the North, 16 6 in the South, 20 4 in the East, and 22 0 in the Central To the principal infectious diseases 10,280 deaths were referred during the year, of these, 1314 resulted from small-pox, 2360 from measles, 560 from scarlet fever, 1159 from diphtheria, 1876 from whooping cough, 537 from enteric fever, four from simple continued fever, and 2470 from diarrhœa, but not one from typhus fever These 10,280 deaths were equal to an annual rate of 2 21 per 1000, against 2 49, 2 23, and 2 22 in the three preceding years Among the various metropolitan boroughs the death rates from these principal infectious diseases ranged from 0 81 in Hampstead, 1 17 in Stoke Newington, 1 28 in the City of Westminster, 1 38 in the City of London, 1 49 in Kensington, and 1 59 in Greenwich, to 3 06 in Bermondsey, 3 10 in Southwark, 3 13 in Fulham, 3 18 in Finsbury, 3 31 in Stepney, and 3 53 in Shoreditch. The 1314 fatal cases of small pox exceeded the average by 1250, of these 1314 deaths 734 were registered during the first quarter of the year and 507 during the second quarter, among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Holborn, Shoreditch, Bethnal Green, Stepney, and Poplar The 2360 deaths referred to measles were 366 below the average number in the 10 preceding years, this disease was proportionally most fatal in Fulham, Chelsea Finsbury, Shoreditch, Southwark, and Bermondsey The 560 fatal cases of scarlet fever were 300 below the corrected decennial average, the highest rates from this disease were recorded in St. Pancras, Finsbury, Southwark, Lambeth, Camberwell, and Deptford The 1159 deaths from diphtheria were only slightly more than half the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, St. Pancras, Finsbury, *the City of London, Poplar, and Lewisham* The 1876 fatal cases of whooping cough showed a decline of 285 from the average number in the ten preceding years, the greatest proportional mortality from this disease occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Southwark. The 541 deaths referred to "fever" were considerably below the corrected average number, among the various metropolitan boroughs the highest "fever" death rates were recorded in Hampstead, St. Pancras, Islington, Hackney, Shoreditch, and Poplar The 2470 fatal cases of diarrhœa were 1220 below the average number, this disease was proportionally most fatal in Fulham, Finsbury, Shoreditch, Stepney, Southwark, Bermondsey, and Deptford In conclusion it may be stated that the mortality in London last year from these principal infectious diseases in the aggregate was 17 0 per cent. below the average.

Infant mortality in London last year, measured by the proportion of deaths among children under one year of age to registered births, was equal to 139 per 1000, against 166, 158, and 148 per 1000 in the three preceding years The rates of infant mortality in the various metropolitan boroughs ranged from 87 in Hampstead, 107 in St. Marylebone, 115 in Stoke Newington, 119 in Hackney, and 125 in Limehouse and in Woolwich, to 154 in Finsbury and in Poplar, 155 in Bethnal Green and in Bermondsey, 166 in Southwark, and 174 in Shoreditch.

THE SERVICES

THE NON COMMISSIONED OFFICERS AND MEN OF THE ROYAL ARMY MEDICAL CORPS.

A COMPREHENSIVE scheme of reorganisation aiming at a differentiation of the duties of non commissioned officers and men of the Royal Army Medical Corps has been under consideration at the War Office. It has been decided to recommend that the non-commissioned officers and men of the corps should be divided into four distinct sections (1) the nursing section, (2) the cooking section, (3) the clerical section, and (4) the general duty section Special attention has been paid to the training of men for the nursing section, who will in future be employed in nursing duties only A very complete scheme for nursing instruction is being drawn up and every effort is being made to develop this section. Her Majesty Queen Alexandra has signified her wish that the most proficient and best conducted male nurses should be admitted to her nursing service and a scheme for carrying out this object, including extra remuneration to such selected non commissioned officers and men and the granting of a special badge to denote the distinction that has been conferred upon them, is under consideration To the general duty section will be allotted those duties in hospitals only indirectly connected with the care of the sick. Advancement to a higher grade of orderly and promotion (except to a limited extent in the clerical and cooking sections) can only be obtained through the nursing section. Revised rates of pay are under consideration with the view of making the nursing section the most important and attractive. It is believed that the employment of specially selected men in nursing only with adequate remuneration will attract to the corps the best class of men, while the admirable courses of instruction for which officers commanding hospitals and matrons are responsible should enable men to qualify themselves for posts in civil life on retirement.

ROYAL ARMY MEDICAL CORPS.

Captain C B Lawson proceeds to Woolwich for duty as Clinical Pathologist at the Herbert Hospital on expiration of his appointment at Charing Cross Hospital. Lieutenant-Colonel A. F Franklin is nominated for service in the Bengal Command, vice Major Forrester, *tour expired.* Major W T Swan has joined at Portsmouth for duty

The undermentioned Captains to be Majors (dated Jan 31st, 1903) —E E Powell, J W Jennings, D S O. E McK. Williams, J C Connor, F W Hardy, W A. Graham, D D Shanahan (Brevet Major), C W H. Whitestone, A. Pearse, and C Dalton.

Captain H. N Dunn, from the Seconded List, to be Captain. Dated Jan 17th, 1903.

Lieutenant M G Sterling is seconded for service with the Egyptian Army Dated Jan. 17th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) 2nd Durham (Seaham) Surgeon Captain L. G Dillon to be Surgeon-Major Dated Feb 7th, 1903

Submarine Miners The Fourth Division Surgeon Captain H. Hay to be Surgeon Major Dated Feb 7th, 1903

Rifle 1st Volunteer Battalion the Royal Scots Fusiliers. Surgeon Major W Sneddon to be Surgeon Lieutenant-Colonel Dated Feb 7th, 1903. 3rd (Cumberland) Volunteer Battalion the Border Regiment Surgeon Lieutenant T G Mathews resigns his commission. Dated Feb. 7th, 1903 1st Volunteer Battalion the Hampshire Regiment The undermentioned officer *resigns* his commission Surgeon Lieutenant W B *Colquhoun. Dated* Feb 7th, 1903. 3rd Volunteer Battalion the Essex Regiment Surgeon-Lieutenant H. N A. Taylor *to* be Surgeon Captain Dated Feb 7th, *1903.*

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

The London Campanies Supernumerary Lieutenant E W Herrington to be Captain. Dated Jan. 27th, 1902.

VOLUNTEER OFFICERS' DECORATION

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force who have been duly recommended for the decoration under the terms of the Royal Warrant dated July 25th, 1892 —*Home District Rifle* 1st Middlesex (Victoria and St. George's) Volunteer Rifle Corps Surgeon Lieutenant-Colonel Frederick Enos Fenton 7th Middlesex (London Scottish) Volunteer Rifle Corps Surgeon Captain James Cantlie *North Eastern District Rifle* 2nd Volunteer Battalion the East Yorkshire Regiment Surgeon Major Alexander Ferrier Angus Fairweather, retired *North Western District Rifle* 6th Volunteer Battalion the Manchester Regiment Surgeon Lieutenant-Colonel Robert Lancelot Sparrow *Scottish District Rifle* 6th (Fifeshire) Volunteer Battalion the Black Watch (Royal Highlanders) Surgeon Major Charles Edward Douglas

THE DUKE OF YORK'S ROYAL MILITARY SCHOOL.

The *Army and Navy Gazette* of to-day (Feb 14th) calls attention to "a remarkably anomalous condition of things" noticed in scanning the "Army List." Our contemporary has discovered that although among the *ex officio* members of the Commissioners of the Royal Hospital, Chelsea, a military medical member—viz , the Director General of the Army Medical Service—finds a place, yet among the *ex-officio* members of the Commissioners of the Duke of York's Royal Military School no military medical member has been appointed The *Army and Navy Gazette* goes on to say "Surely one is quite as necessary in the latter institution as in the former This will have to be remedied without delay, and we understand that a question on the subject will arise when Parliament assembles If the Chaplain-General and Judge-Advocate-General take places as *ex-officio* members of the Duke of York's School, surely a military medical member of rank and experience should be appointed for the sanitation of the institution, and matters connected with the health of the boys must come up now and again for consideration It is now well known that the sanitary condition of the Duke of York's School has been recently investigated, and it is not unlikely that the Secretary of State for War is by this time in possession of the report thereon, the particulars of which will be called for on the reassembly of Parliament We invite the attention of the medical journals to the foregoing comments, and would like to know their views." Our views coincide with those of the *Army and Navy Gazette* that the Commissioners of the Duke of York's Royal Military School should include among them a medical officer of experience and rank

SIR FREDERICK TREVES AND THE SOUTH AFRICAN WAR COMMISSION

The Royal Commission on the South African War resumed its sittings on Feb. 4th. Evidence was given by Sir Frederick Treves, who served with Sir Redvers Buller's army in Natal down to the relief of Ladysmith. Sir Frederick Treves expressed his views as to the over-organisation of the Army Medical Service at the date of the war, the need of decentralisation, and of giving to the individual officer more freedom of action and emancipation from merely clerical work. He gave evidence as to the inadequacy or unsuitability of much of the stores, instruments, and ambulances at the date of the war as to the training of army medical officers, and as to military hospitals generally He also gave explanations as to the recent action of the Medical Advisory Board at the War Office and the steps which have been taken since the war, or are now in contemplation, to reform the defects in the Army Medical Service.

The prizes gained by the members of the London Companies Royal Army Medical Corps (Volunteers) will be distributed on Feb 21st by Major General L. J Oliphant, C.B C V O, at the headquarters, 51, Calthorpe-street, London, W C The distribution will be followed by a dance

Correspondence.

' Audi alteram partem."

NATIONAL HEALTH AND PHYSICAL EDUCATION

To the Editors of THE LANCET

SIRS,—The Scottish poet Burns has given expression to a most excellent prayer, and one suited to almost everybody, in the lines

> Oh, that the Guid the gift wad gie us
> To see oursels as others see us."

The fact that a large proportion of our urban population is unfit for military service has, I believe, been fully known to, and carefully considered by, our German friends for a considerable time while we have been more or less blind to it and have certainly not given to it the consideration it deserves.

It seems to me that Sir Frederick Maurice by his writings and speeches, and you by your leading article in THE LANCET of Jan. 31st, p 315, have done public service by drawing attention to the fact It is, indeed, staggering to learn that out of every five would be soldiers only two are found to be fit for service after two years It is probable that, as you say in your article, this condition is not that of the population at large but only of a certain section of it. The fact that the record is constantly being broken for all sorts of feats of strength, agility, and endurance, such as lifting weights, high and long jumps, foot races, scores at cricket, bicycle rides, and swimming, indicates that the physique of the well to-do classes is improving rather than deteriorating But, on the other hand, the existence of a large section of the community, and that, too, the one which is most readily available for recruiting, having such a poor physique that only two out of every five are fit for military service is, as you most truly say in your leading article, an appalling fact. Nor is the condition a serious one only because it prevents us from getting the number of soldiers we need when an emergency arises, it is serious also from the civil standpoint, for if these men are unfit for military service what are they good for? Poor in physique as they all are, and poor in mental capacity and power of application as you suggest many of them are, What becomes of them? Many of them probably marry girls as weak as themselves and have children, some of whom go to swell the lists of infant mortality, some to join the criminal classes, while others grow up more weak and incompetent than their parents It is probable that for the existence of this class the medical profession is to a considerable extent responsible. For by its increased knowledge and more energetic application of medicine and hygiene children are now reared who, under less favourable conditions, would have died in infancy The harm which it has thus done the medical profession must now strive to undo by doing its best to secure that children shall not merely grow up, but shall be sufficiently strong and healthy to fit them for the battle of life. How this is to be done is a problem by no means easy to solve, in search for a solution, as Sir Frederick Maurice truly says one makes many mistakes and has often to change one's impressions, and therefore it is with the utmost diffidence and merely in a tentative way that I should like to mention some ideas which have occurred to me in regard to it First of all, we want information as to (1) the causes of physical deficiency, (2) the best means of remedying the defects, and (3) the best means at present available in case that the best means possible cannot as yet be applied.

Information having been obtained on these points the next thing is its practical application It is obvious that such tasks could only be undertaken by the Government and they ought properly to be undertaken by a board of health if such a board existed. In the absence of this much needed board I suppose the best means of obtaining information would be the appointment of a small commission, regarding the composition of which the Royal Colleges of Physicians and Surgeons might fitly be consulted. As you truly say in your leading article "No purpose can be served by attempting to answer a question of such a size as, What are the methods by which our national health can be improved?' But the scope of the inquiry might be limited to the three chief points insisted upon by Sir Frederick Maurice—namely, deficient teeth, flat-feet, and generally weak physique. The commission might ascertain to what extent decayed teeth are present at different ages among the children attending the Board schools throughout the kingdom. They might try to ascertain also how far the presence of decayed teeth coincides with the absence of phosphate of lime and silica in the food. If these substances be absent or deficient we can no more expect a child to have strong teeth than we can expect a hen to lay eggs with well formed shells when it is not supplied with lime in its food. The perfection of modern mills and the consequent separation of the outer part of the wheat and the mineral matter it contains from the starchy matter which goes to form white bread is probably responsible to some extent for decayed teeth. Secondly, the occurrence of flat-foot at different ages should form part of the inquiry and along with this might go an examination of the development in the calves of the child's legs. Thirdly, they might seek to find out how far early marriages are due to youths and girls having nothing to do after their hours of labour are over excepting to walk about with one another and if this be a cause how far its action might be prevented by providing such occupations and amusements as would not only fill up their leisure time but tend to develop them physically mentally, and morally

Until such information is obtained it is impossible to speak with certainty as to the best means of removing the physical deficiencies to which Sir Frederick Maurice has drawn attention. It seems to me probable, however, that though decay in teeth, like other nutritive phenomena, depends upon the condition of the body as a whole, especially of the nervous system, yet it may be greatly influenced by diet and cleanliness.

Of diet I have already spoken, but attention to cleanliness of the teeth is also of great importance. Caries is often started by acids formed by the decomposition of particles of food lying between the teeth. When the teeth are healthy and strong they may defy the attacks of such acids, but where they are weak they undergo erosion and begin to decay. During the day the teeth are kept more or less clean through being washed by the alkaline saliva and rubbed by the tongue, but during the night particles of food may lie between them for many hours and decompose. The bad effects of this might be greatly lessened by children systematically cleaning their teeth, especially at night. The expense of tooth brushes renders their employment out of the question by the poorer classes, but all that is required is a lucifer match which has already been used. One end of this is cut into a wedge shape and passed between the teeth, so as to press out any particles of food that may be lodging between them. It should also be drawn round the base of each tooth close to the gum so as to remove any adhering tartar. The expense of such treatment is *nil*, the trouble is very small, and the gain from it would be very considerable.

For flat-feet balancing exercises on the toes might be regularly given to school children, but they ought to form only a part of general physical training which should be as compulsory for every child as learning the "three R's." If, as I believe early marriages are partly due to want of suitable occupation and amusement in leisure hours, this might partly be avoided as far as men are concerned by developing their interest in volunteering through regular training at school in the use of a rifle between the ages of seven and 14 years. Their interest might be kept up by rifle and pistol saloons in which they could learn to aim with precision both at stationary and moving objects. The success that has been obtained by Colonel Fox in the development of young recruits by physical exercises shows how extraordinary the benefit is which youths derive from such exercises, and if they were systematically employed in schools many of the recruits who are now rejected would probably be well over the mark of efficiency, while their training in the use of the rifle would enable them to learn all the necessary drill much more quickly than at present and leave them with more spare time during their service. In regard to the employment of their spare time we might, I think, with advantage take a lesson from the Russian army, and upon this point Mr. Francis H. E. Palmer makes some remarks which are so apposite that, with your permission, I should like to quote them entire.

"Military training has naturally produced the most striking results among the lower classes as it has served to develop the very faculties in which the peasantry are most deficient. The recruit drawn from the easy going life of the village, where he seems incapable of doing anything except as a member of his artel, is suddenly transported into a new world in which many moral qualities that have hitherto lain dormant are called into play. Strict obedience is already a part of his very nature but the necessity for order, exactitude, punctuality, and alertness is impressed upon him at every moment. A Russian peasant or workman upon the completion of his military service can nearly always command from 25 to 50 per cent. higher wages than those who have not had this advantage. It is not in moral training alone, however, that the lower classes have benefited by military service. Only a very small part of the multifarious requirements of the Russian army and navy could hitherto be supplied by private industry, and the Government has been compelled to convert itself into a colossal manufacturer and universal provider. Private industry has been fostered, it is true, whenever possible, but nevertheless the Government has been compelled in almost every branch to take the initiative from the weaving of cloth for the soldiers' uniforms to the making of common or scientific instruments. In the army almost every trade is carried on and rarely does a recruit return home when his military service is over without having gained some technical knowledge that greatly increases the value of his labour."[1]

If the army were thus converted into a huge technical school and manufactory, in which all the uniforms shoes, saddlery, &c., were made, the expense of maintaining the army would be so much lessened that we might hope for a marked diminution in taxation, whilst the men trained in it after their return to civil life would be able to support their wives and families instead of becoming a burden on the ratepayers. I am, Sirs, yours faithfully,

Feb. 10th, 1903. LAUDER BRUNTON.

THE RISE OF BLOOD PRESSURE IN LATER LIFE.

To the Editors of THE LANCET.

SIRS,—The arguments on the subject of my paper on arterial pressure[1] in elderly persons come, to my honour, from correspondents so eminent that I must ask you again to publish a brief reply.

Sir William Broadbent's argument is, I think, that there is increased peripheral resistance, the area of which he places in the "capillaries," but that "it need not be viscosity in a physical sense" (I do not perceive any alternative sense?). This proposition is true, no doubt, in the healthy circulation the pressure in the capillaries is higher than the mean pressure of the system as a whole. Sir William Broadbent proceeds to discuss the phenomena of capillarity, which is treacherous ground to enter upon, as capillary phenomena are modes of surface tension and apply to open (air-containing) tubes standing in solutions having a free surface and under the uniform pressure of the atmosphere only. The capillary vessels of the body contain no free air, while, on the other hand, the contents are under a mean pressure above that of the atmosphere. If we turn away from surface tensions and consider only the phenomena of adhesion of surfaces, as, for example, the wetting of the surface of a slip of glass dipped into water, which glass when dipped into mercury had not been wetted—keeping to these simpler, and I think more apt, of the phenomena quoted I would point out that if the blood wet the wall of the capillary the wetting layer ceases to move while the rest of the blood flows on; thus, practically speaking, no energy is lost. If, however, the blood be so altered as not to wet the wall (as the mercury did not wet the glass slip) the outermost layer or cylinder of blood remains no longer stationary, it is forced along with the rest, and friction against the wall, with loss of energy, ensues. There may be, as Sir William Broadbent suggests, some change of this kind; the blood may lose some adhesion to the capillary wall; but such a supposition is highly speculative and to me the speculation seems an unlikely one. Again, projections from the walls, such as would set up contrary currents or "eddies," would obviously imply loss of energy; but such knotty places belong rather to arteries than to capillaries. Now let us suppose, what I think to be more probable, that the outermost cylinder of blood in the tube always wets the wall, and, so wetting it, remains stationary—changing, that is, by molecular processes only. Then, as in the normal state, this layer may be disregarded—and we shall regard the axial stream and the layers nearer and nearer to the still envelope. Of these cylinders within cylinders—for so we may reason of the blood stream—we know that the more axial travel the more rapidly; or, conversely, that the outer layers travel more and more slowly in the degree of their remoteness from the central or axial current. At no two points of a radius of a transverse section is the rate the same; it falls as we move from centre to circumference. Yet how can such differential rates be possible? By continuous deformation of the blood stream; by the shearing force of the more inward cylinders as they slip past the more outward. In the great retardation due to this internal friction of the several layers of blood one upon another a large part of that energy is lost which is continually replaced by the pressure head (the left ventricle). The loss amounts to at least 100 mm. of Hg per second. Were the vessels filled with water this internal friction would be less; if with alcohol less still; but not even alcohol is free from "viscosity." If the vessels contained treacle the shearing frictions would be so great as quickly to raise the friction coefficient to an equality with the maximum pressure within the left ventricle, when, of course, the circulation would stop. I did not pretend to have proved that in senile hyperpiesis the viscosity of the blood is increased; I suggested, and suggest still, that as in healthy capillaries the viscosity of the blood is the main factor in peripheral resistance, we should try first to estimate the variations of this factor which we know rather than to assume the intervention of a new and unknown factor At any rate, let us try to establish a standard of blood viscosity, as yet we have made no attempt to find even a method for its estimation. But since my paper was read, my colleague, Dr Graham Smith, has suggested such a method to me, of which, if it prove to be valid, we shall hear more hereafter

---

[1] Russian Life in Town and Country. By Francis H. E. Palmer. London: George Newnes Limited. 1901. p. 260.

[1] The full text of this paper which was read before the Royal Medical and Chirurgical Society on Jan. 13th will appear in our columns shortly.

Sir William Broadbent argues with Sir Douglas Powell that this alteration of the blood—namely, that it wets the wall less—is due to admixture of impurities, the products of imperfect metabolism. I must repeat that this seems to me at present to be sheltering under a phrase. For my part I also have hinted at this line of research, so have Dr Haig and others. But who will try the experiments? Does blood into which, let us say, purin bodies have been introduced wet membranes less than normal blood (as Sir William Broadbent suggests? Or, again, is it of higher viscosity, as I suggest? And if the latter be the case, has the former factor any existence at all?

For the rest of Sir William Broadbent's letter I am especially grateful The views which he so powerfully supports I brought before the Hunterian Society in equivalent terms a few years ago but was little heeded The German schools continued to hold, with von Basch and the rest, that senile hyperpiesis is due to arterio-sclerosis, and if at the outset arterio-sclerosis be not discoverable, then to latent arterio-sclerosis, the French school continued to assert that in these changes should be recognised not only a primary arterio-sclerosis but also a primary cardio-arterio-sclerosis—a wear out all round—whereas in my opinion the heart in uncomplicated cases, so far from being a skulker or a cripple, dies in the trenches. The English school meanwhile has spent most of its time in disputing whether the middle coat of a thickening arteriole is primarily hypertrophied or degenerated and has not settled the point yet. I believe—and this is a contribution to Dr. Russell's point of view—that the muscular coat of the artery increases, but as that of the heart increases, under abnormally high mean tensile stress, and that as in the heart, so in the artery, the hypertrophy is somewhat fugitive and tends to early decay Dr Russell seems, if I read him aright, still to maintain that arterial spasm comes first and raises the mean arterial pressure, an opinion which from the beginning I have contested, that if universal it would have this effect is true, but so long as compensatory mechanisms are intact it never is universal, nor nearly so. However I must skip the rest of Dr Russell's letter, which I read with sore discouragement. One narrow purpose I thought by long and ascetic discipline in letters to have attained—namely, the negative virtues of austerity, order, and precision, that, whatever my stuff, my style should be concise, lucid, and definite. And, after lifelong lopping, stripping, and drilling, Dr Russell tells me that by "literary garnish my style is unintelligible to the ordinary mind!" Garnish! which I detest in all the arts. How hard life is! Other critics have said, and said it in print too, that I had become too condensed and allusive, presupposing in the reader knowledge which he does not always possess

O glücklich! wer noch hoffen kann
Aus diesem Meer des Irrtums aufzutauchen
Was man nicht weiss das eben braucht man
Und was man weiss kann man nicht brauchen."

I am, Sirs, yours faithfully,

Cambridge, Feb 9th, 1903 T CLIFFORD ALLBUTT

To the Editors of THE LANCET

SIRS,—While feeling some timidity in entering the lists with the distinguished disputants who have recently addressed letters to THE LANCET on the above subject I am tempted with your permission to do so, both on account of its importance to the physician and of the interest I have long taken in it. The fact that there is so little unanimity in regard to so comparatively simple a point as the mechanism of protracted high pressure in the systemic arteries, shows at once the difficulties surrounding the science of medicine and how much how very much, we have yet to learn.

The chief points at issue in regard to these cases of protracted high pressure would appear to have reference to—(1) the situation of the morbid resistance, whether e g, it is located chiefly in the arteries or capillaries, and (2) the nature of the resistance, how far, e.g., it is attributable to active vascular contraction and how far to augmented frictionality (if I may be allowed the term) of the blood. Sir William H Broadbent holds that it "has its primary seat in the capillaries" and that it is due to an alteration in the blood which so influences the vital reaction between that fluid and the capillaries as to interfere with the normal easy flow through these vessels—he assumes, as it were, an increased vital frictionality Professor T Clifford Allbutt attributes the essential cause of the morbid resistance to an increased viscosity of the blood by virtue of which (presumably) its mechanical (as distinguished from vital) frictionality is increased, while he is not disposed to assign to active vascular narrowing any influence in effecting a long sustained high pressure. Finally, Sir R Douglas Powell and Dr William Russell place the chief resistance in the arteries and attribute it to a generalised hypertonus of them

We shall, I think, be helped to a decision on these questions by first considering (1) the situation of the chief vascular resistance under strictly physiological conditions, and (2) how this resistance is modified physiologically 1. It is now some years since you were good enough to publish in THE LANCET a communication from me in which I pointed out that, contrary to the opinion then prevailing, the resistance in the capillaries is normally so small as to be practically negligible. This conclusion is now, I believe, generally accepted among physiologists. It is also generally recognised by them that the large and moderate sized arteries offer very little resistance to the current, and that the chief vascular resistance—say five sixths of the total amount—is located in the arterioles 2 It is equally certain that physiological modifications of vascular resistance are almost wholly due to active alterations in the calibre of these same arterioles, modifications in the frictionality (vital or mechanical) of the blood playing but an infinitesimal part. Were the blood as thin and mobile as spirit, a wide spread arteriolar spasm would yet be adequate to augment resistance to the furthermost limit, and to cause a corresponding augmentation in arterial blood pressure, and, on the other hand, even were the blood of semi tarry consistence it would still, given a widespread arteriolar dilatation, rush with an all too fatal facility into the veins, causing the arterial blood pressure to sink to a few mm. Hg It cannot, indeed, too emphatically be insisted upon that, normally at all events, vascular resistance is essentially arteriolar resistance, one which is placed in a certain part of the systemic circuit for a special physiological purpose, and that the most complex and colossal vascular system—as of the whale, e g—offers in the absence of this arteriolar resistance but a feeble obstacle to the onflow of blood. Further, that the degree of systemic arterial blood pressure is essentially dependent upon the degree of arteriolar resistance a widespread and pronounced arteriolar dilatation lowers arterial blood pressure to a few mm Hg let the heart beat never so vigorously, while the opposite condition leads, except in cases of extreme cardiac failure, to supernormal pressure I say *except in extreme cardiac weakness*, for although it is true, as Dr Russell contends, that general arterial hypertonus does not necessarily go along with augmented pressure, yet in my experience the pressure is only low in cases of hypertonus when the heart has come to the very end of its tether, provided only peripheral resistance is high we shall often find arterial pressure ruling high even in cases of considerable cardiac weakness, as may frequently be observed in the last stages of granular kidney when the failure of the heart has reached the stage of pulmonary engorgement and general anasarca.

Seeing then, that the normal vascular resistance is mainly situated in the arterioles and how overwhelming is the part played by arteriolar contraction and dilatation in modifying resistance physiologically, one is naturally led to ask whether it is needful to seek elsewhere for protracted morbid resistance, or for any other mechanism in explanation of it? In other words, cannot we satisfactorily account for these cases on the supposition that there is a widespread arteriolar contraction? The more so if it can be shown that such an arrangement makes for a good end, as I believe it does. It is admitted by all that the primary cause of persistent high blood pressure is a toxæmia, and what, I submit, happens is this in response to the action of the poisoned blood all (or most) of the systemic arterioles contract, save those within the kidneys which dilate, the effect being greatly to increase the flow and pressure of blood within the kidneys, and thus to favour the elimination of the poisons by these latter This view which I have already set forth in the pages of THE LANCET[1] is strengthened by the remarkable observations of Dr Russell to the effect that in what he calls arterial hypertonus the muscular coat of all (or most) of the systemic arteries is hypertrophied, *while that of the intrarenal arteries tends to be atrophied* Let us not lose sight of the physiological aspects of disease. Are we to regard the heightened blood pressure in the cases we are considering as an instance of mere blundering on the part of the organism? Are we to suppose that the organism would permit the maintenance through long years of a morbidly high vascular resistance which by the strain it puts on the heart and arteries inevitably leads to their undoing—are we, I say, to suppose all this when in the twinkling of an eye that resistance could, by the opening of the arteriolar flood gates, be effectually lowered, even to the point, if need be, of inducing collapse? That seems to me an unwarrantable assumption. The animal organism possesses elaborate means of coping with its maladies and in so doing displays an infinitely greater wisdom than the wisest physician can ever hope to attain to Bearing this fact in mind, can we doubt, if a low arterial pressure would advantage the organism in the cases in question, that the organism would very soon bring it about, seeing that the means of doing so are ready to hand? We must conclude, therefore, that the high blood pressure in these cases plays a useful part. The view advanced by Sir George Johnson and adopted by some, that the arteries contract for the purpose of protecting the tissues from their poisoned contents, credits the organism with a shortsightedness which I am loth to attribute to it. Such a course could only defeat its own ends by diminishing the circulation through the kidneys as well as through other parts, and thus actually diminishing the elimination of the poisons apart from wearing out the heart and arteries.

---

[1] THE LANCET June 8th 1901 p 1627

Professor Allbutt doubts whether vascular spasm is capable of maintaining a protracted increase of resistance, though he admits the indefatigability of the arteries, indeed, the average condition of the arterioles throughout life is one of spasm, temporary local relaxations occur, it is true, but taking the arterioles at large their active contraction at any one moment is considerable, for otherwise death would inevitably occur from bleeding into the veins The life of the organism is, in fact, as much dependent upon the tonic contraction of the arterioles as upon the rhythmic contraction of the heart. And if these vessels are capable of so much, why, I would ask, should they not be capable of a little more? and it needs, be it observed, but a moderate increase in their normal contraction to cause a substantial augmentation in resistance Have we not, moreover, both clinical and anatomical evidence of the existence of sustained arterial hypertonus, clinical in those cases of "tightly contracted vessels" to which Professor Allbutt himself refers, and anatomical, in the cases of hypertrophied media, observed by Dr T D Savill, Dr Russell and others?

The fact that normally the resistance in the capillaries is infinitesimal appears to me to tell against the view that they constitute the chief resistance in cases of high blood pressure. I cannot think any altered condition of the blood could without destroying life right out, so increase the friction between the blood and the capillaries as to change a capillary resistance of from 1 or 2 Hg mm. to one of say 50 or 60 Hg mm. or more—that is to say, by from 20 to 30 times its normal amount. If, on the other hand, we assume the morbid resistance to reside essentially in the arterioles which normally offer a resistance of, say, 70 Hg mm., we have but to postulate an increase in this resistance by a fraction of its normal amount in order to get a very substantial increase. Again, would not a resistance of from 50 or 60 Hg mm in the capillaries render the occurrence of shock impossible by preventing the sudden rush of blood into the splanchnic veins upon dilatation of the corresponding arteries? And is there any evidence that patients with protracted high arterial blood pressure are proof against shock? These considerations lead me to doubt whether the systemic capillaries can take any but a very moderate share in the production of the morbid vascular resistance which we are considering

One word more before I end this very imperfect letter I find it difficult to accept the view expressed by Sir Douglas Powell to the effect that loss of arterial elasticity "tends to a low blood pressure and at the same time to cardiac hypertrophy" Given a healthy heart, is not the arterial blood pressure the measure of vascular resistance? And does not low arterial blood pressure (I am still assuming the heart to be healthy) imply that the vascular resistance which the heart has to overcome is correspondingly low? Does it not, in other words, imply diminished rather than increased work for this organ?

I am, Sirs, yours faithfully,
Wimpole-street, W Feb. 8th, 1903 HARRY CAMPBELL

ORGANIC COMPOUNDS OF ARSENIC

To the Editors of THE LANCET

SIRS,—With regard to Sir Thomas R Fraser's paper on Arrhénal and his conclusions as to the physiological inactivity of organically combined arsenic, it may be of interest to point out that Robert Bunsen 60 years ago demonstrated the comparatively non toxic nature of the cacodylic compounds He injected 0 35 gramme of cacodylic acid into the marginal vein of a rabbit's ear without producing toxic symptoms Later Rabuteau determined the minimum lethal dose for a medium sized bitch as two grammes (about 30 grains or 16 grains of arsenious acid)

I am, Sirs, yours faithfully,
J M FORTESCUE-BRICKDALE, M A., M.D OXON.
Clifton, Bristol, Feb 9th 1903

THE MEANING OF URIC ACID AND THE URATES

To the Editors of THE LANCET

SIRS,—If I may be permitted to make a few remarks in reply to those of Dr Woods Hutchinson[1] I would say that the method I have used for the estimation of uric acid was subject to some criticism when it first appeared in 1885, but that Professor Haycraft has long since vindicated its position and it is to be found to-day, as the bibliography of my book ("Uric Acid") shows, in most European standard works of reference. I think also that anyone who will read carefully the experimental portion of my book will see that the chief results there recorded are far beyond the range of any single method, and can be demonstrated by many methods, even by a third year student of physiology, with no more elaborate instrument than the point of his finger For the food poisoning which has been dignified by the names of many diseases produces two main classes of effects—(1) those general on the circulation, and (2) those local on the tissues, and the former are so very obvious that it may be said to-day that no taker of poisons (flesh, tea, &c.) ever has a capillary circulation as quick as that of those who abstain from poison, the difference even amounting to 50 per cent, nor have the self poisoners as good a blood condition (blood decimal or worth), the difference here amounting to quite 20 or 30 per cent. I have often offered rewards of £5 and upwards to anyone who will produce a habitual taker of flesh and tea with a circulation and blood colour equal to my own. No one has as yet claimed the reward, perhaps Dr Woods Hutchinson will now do so A glance at the gums in good daylight and a touch with the finger on the front of the chest generally suffice to dispose of the claims of all self poisoners, as I demonstrated to some of those who attended the recent debate on Professor T Clifford Allbutt's paper on the Rise of Blood Pressure in Later Life (see THE LANCET, Jan. 17th, p 171), and this rise of blood pressure in later life with its collæmia (uricacidæmia) and anæmia is as simple and easy to explain for those who understand uric acid pathology as the rheumatism and chlorosis in girls of 13 and 17, which it exactly parallels. So much for the great circulation group of uric-acid poisoning, though I may say in passing that the intestinal putrefaction on which Dr Woods Hutchinson lays so much stress can easily be proved to be a mere result of the defective circulation which uric acid produces. Put the circulation right and no intestinal antiseptics will ever be required, for stomach, liver, and intestines will be able to act normally As to the local group of uric acid troubles it is my experience, and that of hundreds of others, that to abstain from swallowing these poisons for from 18 months to two years means relief or cure of all arthritis and local pain which is due to uric acid, and that any relapse into taking of uric acid promptly brings them back again It is to the gradual spread of a knowledge of these simple facts and to the practical results which follow their application that the present wide acceptance of my views is due, and this has astonished Dr Woods-Hutchinson because he has confined himself too much to ancient theories and has made too small an attempt to examine modern facts which can be demonstrated in a few moments. With regard to his conclusions I may point out that I, for one, have never suggested the limitation of nitrogenous food, except in relation to body-weight, and there I have always adopted the *ordinary* physiological standard of from nine to ten grains of albumin per pound per day Finally, I assert, without fear of contradiction, that the gouty or uric-acid diathesis is a myth, the product of past ignorance, and that all those who cease to swallow uric acid will also soon cease to be lethargic, anæmic, and puffy, walking or limping demonstrations of its poisonous effects. Of many such with their short and miserable lives it may be truly said, they "do not die, they kill themselves."

Brook-street W., Feb. 9th 1903.

ASEPTIC AND ANTISEPTIC SURGERY

To the Editors of THE LANCET.

SIRS,—Writing under this heading in THE LANCET of Feb. 7th, p 347, Mr W Watson Cheyne says that the return of buried sutures is due to their infection at the time of operation and not to any defect in the nature of the material used. With this statement most surgeons will agree and admit that the infection is due to contact with the hands of the operator or his assistants. Mr Watson Cheyne seems to think that it is not due to want of initial disinfection of the hands but to the neglect of use of chemical solutions during the progress of the operation and he goes on to say that the 'aseptic method" lays too much stress on marble floors and rounded corners and neglects to enforce disinfection of the hands and general care during the conduct of an operation. This is certainly not my experience and I fail to see why a person working in a clean room should be less careful than one working in a room that is hard to clean. In addition, I believe that a student who is made to change his boots and to envelop himself in a clean overall is not less likely to clean his hands than one who simply takes off his coat, puts on an old mackintosh apron, and pins a carbolised towel round his neck. It is then stated that the nurse trained in aseptic methods is likely to pick up an instrument *off the floor to return it as sterile after* two seconds in the steriliser, to touch the handle of the door, or to soil her hands in some other way and then without disinfecting her hands to return and to help at the operation. This certainly cannot be laid at the door of aseptic technique which, above all things, teaches the value of soap, even if it tends to minimise the use of chemicals

On the other hand, a student or nurse trained in the antiseptic school is prone to place too much reliance on a wash in chemicals and too little in hot soap and water In the same way a person trained to believe largely in disinfection by chemicals is more likely to think "medicated" cotton wool sterile than one who has been taught that dressings are to be sterilised by pressure steam or boiling water. In spite of some experiments performed at Liverpool it is still unlikely that the human skin can with any certainty be rendered sterile. A method that bears this in mind and teaches that dressings, swabs, ligatures, and instruments after being sterilised in the most perfect method known should be handled as little as possible and that the hands should be kept out of wounds or covered with boiled rubber gloves is better than one that lays great stress on the use of chemical disinfections. In this connexion it is well to remember that Bulloch and Andrewes have recently stated that some pus-producing organisms are extremely resistant to the persalts of mercury I have seen both methods carried out side by side over a considerable period of time, and in this instance the aseptic method was not behind the antiseptic in results. The adoption of the aseptic method does not involve the abandonment of suture in layers, silk, silkworm gut, all sterilised by heat, can be buried with safety Judging from recent literature the Americans have not given up suture in layers, but some operators by the adoption of a particular form of knot have contrived to withdraw their continuous buried sutures after healing is complete.

I cannot see that there is any great difficulty in carrying out the aseptic technique in private practice. At St Thomas s Hospital boxes containing sterilised towels, swabs, and dressings have for some time been provided for the staff. If these are not to be obtained boiling water is always available and by its means all that is required can be as efficiently sterilised as by chemicals. There is certainly no harm in weak antiseptic solutions, but when strong ones are used to disinfect the skin the hands of some operators become a positive danger in themselves

In conclusion, I doubt that anyone who has worked with the aseptic method will agree with Mr Watson Cheyne that it leads to a lax and careless technique

I am, Sirs, yours faithfully,
CUTHBERT S. WALLACE.

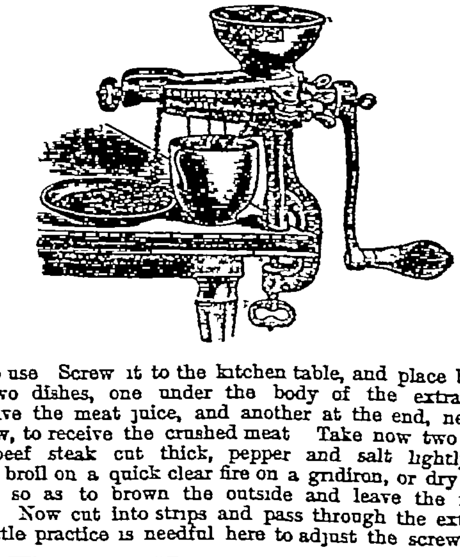
SPECIAL BEEF-TEA.

To the Editors of THE LANCET.

SIRS,—Having studied a remarkable article by M. Charles Richet, of the Faculty of Medicine of Paris (*La Semaine Médicale*, July 18th, 1900), my interest in the use of raw meat and raw meat juice was greatly revived, and I realised that so far I had not given the matter fair trial Of the value of such nutriment, especially in cases of exhausting diseases such as tuberculosis in its various forms, I was quite satisfied. However, I was met by such difficulties in inducing patients to drink raw meat juice that I was *driven to make experiments in order to render* it more palatable and acceptable. I tried it administered in a coloured glass, also mixed with port wine, also sweetened, and even in effervescence. All failed in most cases. At last I succeeded in accomplishing the end and I now publish the method *after more than two years'* trial and *experience*. We are all familiar with the differences of opinion regarding the value of beef-tea. Some set it down as almost worthless, others praise it too highly The truth seems, as usual, to lie between. My own impression is that beef tea, as ordinarily prepared, is mainly a mild stimulant, especially of appetite, and of small nutritive value.

I shall now offer a new receipt for a "special beef tea," in which the nutritious elements are preserved, and reinforced, as far as possible I may premise that it is mainly a device for administering raw meat juice in a form so palatable and concealed that even the most delicate and fastidious do not refuse it, but on the contrary, relish it I have used it extensively for the last two years, and with most satisfactory results. The receipt is as follows —First procure an "Enterprise Meat Juice Extractor" and study its construction and use.[1] It is simple and comes asunder easily Before use, and when it needs cleaning, pour scalding water through and over it [2]



To use Screw it to the kitchen table, and place beneath it two dishes, one under the body of the extractor to receive the meat juice, and another at the end, near the screw, to receive the crushed meat Take now two pounds of beef steak cut thick, pepper and salt lightly, and then broil on a quick clear fire on a gridiron, or dry frying-pan, so as to brown the outside and leave the interior raw Now cut into strips and pass through the extractor. A little practice is needful here to adjust the screw at the end of the extractor, so as to get all the juice to pour out from the slot in the under surface of the instrument. If the screw is tightened up too much the pulped meat will come through with the juice. If, on the other hand, the screw is left too far out the meat is not compressed sufficiently and the quantity of the juice is reduced. A little experience enables the operator to strike the right point. Two pounds of beef should give about two wineglassfuls of juice Collect the juice and separately collect the crushed meat. Strain the juice through muslin and leave it aside till wanted Next take the crushed meat, pour on it a pint and a half of cold water, and let it stand for two hours. Then simmer very slowly for two hours, set it aside, and when cold strain off the clear fluid

---

[1] This Extractor is of American make, imported by John G Rollins and Co. Old Swan Wharf London, and sold in Dublin by Fannin and Co., 41, Grafton-street and Messrs. Hughes, 23 Dawson-street.

[2] A similar meat juice extractor was described in THE LANCET of Oct. 26th, 1901 p. 1130—ED L.

For use, heat this clear beef tea and when it is just fit to drink—say at a temperature of 105° to 115° F , just comfortable to swallow—add to it the strained raw meat juice Flavour with salt and serve. Observe particularly that the meat juice must be added when the beef tea is so far cooled that the patient can drink it If the beef tea is hotter (say 160° F or over) the albumen of the meat juice coagulates and its nutritive value is deteriorated. Beef tea thus prepared is very palatable and can be given to patients without their knowing that they are taking raw meat juice—a very important matter as many persons would not touch raw meat if they knew it. For those who like a full flavoured beef tea half a teaspoonful of "Maggi's essence aux fines herbes" may be added. This excellent condiment can be had from Cosenza and Co , 95, Wigmore street, London, W This beef tea may be rendered still more nutritious by the addition of some farinaceous element, as follows. Before the addition of the raw meat juice bring the clear beef tea to boiling point and then dust in a teaspoonful or so of Groult's tapioca and boil for ten minutes or until the tapioca is transparent, or add to it a teaspoonful of fine arrowroot or cornflour, blended in a tablespoonful of water, boiling then for ten minutes. Now let the beef tea cool so as to be fit to drink, then add the salt or flavouring essence and the strained raw meat juice. I have never yet met a patient who did not like this "special beef tea" and take it willingly

I am, Sirs, yours faithfully,

Dublin, February, 1903 FRANCIS R. CRUISE, M.D Dub

URANIUM SALTS IN CANCER A SUGGESTION

To the Editors of THE LANCET

SIRS,—Any drug that offers the faintest hope in the treatment of cancer seems worthy of a trial. Now, since cancer seems to begin as an overgrowth of the cell, anything that tends to modify this might do good Uranium nitrate when given to animals causes ulceration at the pyloric end of the stomach, but when given to man does not do so, though it doubtless tends to It might be worth an extended trial in certain cases of cancer at the pyloric end of the stomach and it would be interesting to know in what way the cells had been modified as shown by the microscope The action of uranium is specific, since it acts in animals when the drug has not been introduced directly into the stomach. From this one might reason that it would modify an overgrowth of the cell in any part of the body, and that a sterilised injection into a growth, be it cancer or fibroid, might do some good. The claims of a country practice do not allow me to work out all this, and the material is not available My only experience is in the case of cancer of the larynx, where a 1 per cent. spray had a marked effect in checking hæmorrhage and in lengthening the interval between each attack. I have put the idea before some of my medical friends in Liverpool and they think it worth a trial, but as I cannot find any record of its use in this way, I venture to bring it forward Dr S West has used it with some promise in diabetes and has given it in doses of from one-eighth of a grain up to 20 grains three times a day The late Dr Drysdale recorded a cure in ulcer of the stomach. The action of uranium in diabetes has been thought to be due to its helping to eliminate uric acid, and this brings another view of cancer before us It seems to be established that cancer is more common in the well nourished, and it may be that the overgrowth of the cell is due to excess of nutrition over combustion and excretion, thus causing products akin to uric acid to irritate and so cause an increased growth. If this is so, then probably the best drug would be salicylate of uranium when the chemist can make it. For experience teaches me that there is a good deal in Dr Haig's opinion of the value of the salicylates in chronic gouty conditions. Possibly they act by increasing combustion and oxidising uric acid into urea, or in fevers by oxidising the specific virus to render it inert. No one, of course, expects a drug to cure cancer, but it might be possible to modify it in the way that mercury modifies syphilis. When mounted on a theory one is apt to ride it to absurdity, but it may be that such growths as post-nasal adenoids which are far more common in the children of the rich and presumably well nourished than in the children of the poor, may be due to excess of nutrition over combustion either in the mother or child or both. The theory occurred to me before I had heard of uranium and as the drug seemed to offer some chance of success I venture to put it forward in the hope that some may think it worthy of a trial.

I am, Sirs, yours faithfully,
ARTHUR C. WILSON, M B , Ch B Vict

Formby, Feb 4th, 1903.

BRISTOL AND THE NON-VENTILATION OF SEWERS

To the Editors of THE LANCET.

SIRS,—Your Special Commissioner's report on the above *subject*, published in THE LANCET of Jan. 17th, p 202, shows that notwithstanding the long stretch of daily exposed mud or river deposit and its system of non ventilation of sewers Bristol has always had a better *health record than* towns and districts professing to have a system. This, one would think, should have called forth remarks either from the engineers or the medical officers of health connected with towns and districts whose records are not so good as Bristol, and also of towns and districts, including the London districts, whose records have a better average

There cannot be much doubt but that the major portion of sewered towns and districts suffer from systems which are most defective in that the ventilators of the *lower levels poison the atmosphere of the higher levels*, and the leaky sewers of the higher levels poison the atmosphere of the lower levels *viâ* air currents underground, including the channels into the residences formed around drains, water- and gas-pipes, &c., the circulation set up causing a more virulent outbreak of illness in the high portions of the town than in the lower, the higher portion being supposed to be the most healthy and containing as a rule the better class of residents Trusting that even now the question (which is a serious and most important one) may have attention from those able thoroughly to discuss it.

I am, Sirs, yours faithfully

Feb 3rd 1903. D T BOSTEL, Sen.

THE DANGERS OF CALCIUM CARBIDE

To the Editors of THE LANCET

SIRS,—Calcium carbide is a substance which has come into considerable use within the last few years, as it has the unique property of developing a gas which can be used as an illuminant when water is poured on it. Not only is it used for lighting houses, &c., as a source of acetylene gas, but it is extensively adopted all over the country for bicycle lamps. This substance is already the subject of legislative enactments as to storage, &c., on account of its inflammable and explosive character, but I beg to point out that it has been overlooked from the public health point of view and that persons who are compelled to handle it should be protected by provisions of law

My attention was forcibly directed to this matter by a patient who presented himself for treatment for dyspnœa, hæmoptysis, headache, anorexia, and various neurasthenic symptoms, and who exhibited signs of patchy consolidation of the lungs, but who exhibited no rise of temperature or sign of tuberculous trouble. He was a lad, aged 14 years, but quite stunted for that age, and on questioning him to elucidate some cause for his symptoms I discovered that his occupation was to fill tins with calcium carbide and he gave a vivid and graphic description of the hissing sound which was produced when a particle of the substance happened to be inhaled through the nose or get down the throat, as well as the irritant cough and difficulty of breathing which troubled him whilst at work and the comparative ease he at once enjoyed when he got into the air From the violent chemical action which takes place when calcium carbide comes in contact with any mucous surface I suggest that some protection for workers with it is imperative.

I am, Sirs, yours faithfully,

Dublin Feb 5th 1902. J C MCWALTER, M A., D P H

THE MIDWIVES ACT

To the Editors of THE LANCET

SIRS —The passing of the Midwives Act of 1902 devolves a grave responsibility on the nation in order that, as the untrained midwife vanishes, the poor who either cannot, or will not, be attended by medical men may not be left without necessary assistance. A clergyman writes to me, "We have no maternity charity or help of any sort towards doctor or nurse, it is sad to see the suffering from neglect and ignorance and feel utterly at the mercy of these untrained women. How the Act will affect us I cannot guess if it stops the present dangerous system and gives us nothing in its place I am not sure that it will be an advantage. I am sure our poor women won't consider it so They can't afford to engage a trained monthly nurse, especially from a distance, *or to send for a doctor.'*

Now it is to help these remote scattered parishes, as well also as the crowded provincial towns where these untrained women are so numerous and prosperous that I am anxious to gain the sympathy of those able to help First of all, I would enlist the coöperation of the local medical man who feels that the village midwife working under proper supervision would be a help rather than a hindrance to his work—of the busy and often overworked family practitioner who recognises the fact that such women will relieve the pressure by taking those cases that use up his most valuable time and pay so little, if at all and whom he may trust to send for him in good time when surgical skill is required. Then I would, where nursing associations exist or could be started, have one or two midwives attached and thus make use of existing organisations where possible I have done this in my own case, the woman prepays an extra fee of from 5*s* to 10*s*, which is returned to her if the medical man is not required If he is sent for the association guarantees the payment.

In very sparsely populated districts one or two might join together to provide a midwife, and the midwife might be encouraged to combine with her work some occupation not detrimental to her calling In towns the work would become quickly self paying, and I feel that a very moderate outlay would start a sound, substantial work. I cordially invite those interested, and especially medical men who approve of this scheme, to communicate with me, and I would ask others to help me with funds to make a good beginning

I am, Sirs, yours faithfully,

JOSEPHINE JOHNSTONE.

Bignor Park, Pulborough Feb 7th, 1903

THE SURGICAL TREATMENT OF RHEUMATIC FEVER

To the Editors of THE LANCET

SIRS,—From a long experience in South China, I can fully confirm the statements made by Dr A. Haig in his letter under the above heading in THE LANCET of Feb 7th, p 398 Arthritic pains of all kinds are quickly relieved by the salicylates during the cool season, but much harm may follow if given when the thermometer stands above 80° F

I am, Sirs, yours faithfully,

EDWARD HORDER, F R C S Edin

Limpsfield Feb 9th 1903

"'TIS FORTY YEARS SINCE"

To the Editors of THE LANCET

SIRS,—Having had occasion to refer to the lists of the London hospital staffs of 40 years ago as given in the Students Number of THE LANCET of Sept. 20th, 1862, I think that it may interest your readers if I give a brief summary as to the survivorship of these gentlemen. Of course all who held office in 1862 have retired from active hospital work, as life appointments have long ceased to exist, and I shall *only mention those still living*

At St. Bartholomew's Mr Luther Holden, then assistant surgeon, is the *sole survivor* of the hospital staff, and Sir Thomas Smith, K.C V O, then demonstrator, of the teaching staff. At Charing Cross Mr R. Barwell, then assistant surgeon, alone survives At St. George's Sir Henry Pitman and Dr J W Ogle, who were physician and assistant physician, Mr Holmes, assistant surgeon, and Dr W Ogle, lecturer on physiology, survive. At Guy's Sir S Wilks and Dr F W Pavy, assistant physicians, Mr J Birkett, surgeon, and Mr T Bryant, assistant surgeon, remain. At King's College Dr L S Beale, physician, Dr A. B Duffin Dr E. Thompson, and Dr E Liveing, assistant physicians, and Mr Spencer Watson, assistant surgeon, remain At the London Dr R. Barnes, obstetric physician, and Mr J Hutchinson, Mr J Couper, and Mr L S Little, assistant surgeons, survive. At St. Mary's Sir E H. Sieveking, physician, with Sir W H Broadbent (physiology), and Mr A. H. Norton, demonstrator, are the survivors. At the Middlesex Mr Mitchell Henry and Mr T W Nunn, assistant surgeons, and Dr R. Liveing, demonstrator survive. At the Royal Free Mr Thomas H. Wakley and Mr F J Gant, surgeons, and Mr Hasler Harris, dental surgeon, remain. At St. Thomas's Dr E Clapton, assistant physician, Dr H. Gervis, assistant accoucheur, Sir John Simon, K.C.B, surgeon, and Mr Sydney Jones, assistant surgeon, survive. At University Sir Alfred B Garrod, physician, and Sir H. Thompson, assistant surgeon, with Professor Williamson (chemistry), and Professor Oliver (botany) remain. At Westminster Dr P W Latham, assistant physician, and Mr H Power and Mr C Heath, assistant surgeons, and Dr Dupré (chemistry) survive.

I am, Sirs, yours obediently,

HISTORICUS.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Plague Epidemic

THE mortality from plague throughout India is advancing by leaps and bounds This week the total has risen to 19 224 The details published are Bombay Presidency, 8962 deaths, the Punjab, 2442, the United Provinces, 2291, Bengal, 2124, the Central Provinces, 605, the Madras Presidency, 683, the Mysore State, 806, Bombay City, 443, and Calcutta 37 In Poona the disease is raging very virulently, nearly 100 deaths are occurring daily, the normal death rate of the city being 12. In Calcutta a fresh outbreak has started and the figures are running up rapidly This year the general development of plague is more widespread and involves a larger population than at any previous period. The Government has been compelled to abandon the system of inspection for plague on the railways in the United Provinces as hopeless. This inspection is credited with having postponed the invasion of certain areas, but when the disease has once attacked a province precautions on the railways are of no further avail.

Jan. 24th

PRESENTATIONS TO MEDICAL PRACTITIONERS —At an "At Home" held at the Bath Saloon, Truro, on Feb 5th, the Mayor of Truro, on behalf of the subscribers, presented Mr Frederick Harold Carlyon, M.D C M Edin., with an illuminated address and a cheque for £55 as a mark of respect and esteem on the occasion of his leaving for Johannesburg The Mayoress presented Mrs Carlyon with a diamond and sapphire bracelet.—Mr Michael Halpenny L.R.C P L R.C S. Edin., L F P S Glasg, has recently been presented with a gold semi hunter keyless watch and a purse containing a sum of money by the inhabitants of Gilfach Goch. Mr Halpenny recently left Gilfach Goch to practise in Ireland.—At De Keyser's Royal Hotel, Thames-embankment, London, E C, on Feb 4th, Mr Theophilus Hoskin, J P, L.R.C P Lond. M R.C S Eng, was presented by the Master of the Worshipful Company of Makers of Playing Cards with a silver salver bearing the following inscription —' Presented to Dr Theophilus Hoskin J P, by his colleagues on the Court of Assistants of the Worshipful Company of Makers of Playing Cards, in commemoration of his services to the Company as Master, 1901–1902"

THE ORGANISATION OF THE PROFESSION

(From Our Special Commissioner.)

Prompt Formation of an Association by the Swansea Practitioners —The New Organisation Deals with Emergency Vaccinations —It Commences the Battle of the Clubs — The Local Custom of not paying for Attendance on the Wives and Children of Members of Clubs

The medical practitioners of Swansea have set a good example. There are one or more unions of colliery surgeons in the South Wales mining districts, but in the large towns no successful attempt at organisation has been made It is true that at Swansea the need of some such effort was more especially urgent, but what is most required is not always obtained. Some 18 months ago at a meeting of the local branch of the British Medical Association the question of club practice was discussed and a committee was appointed to look into the subject, but the matter fell through and nothing appears to have been done, at least by the British Medical Association. After the lapse of several months a few practitioners met at Mr J Kynaston Couch's house to talk over their grievances in an informal manner Though there were but six practitioners present they nevertheless determined to strive to form a medical union for the express purpose of dealing with economic questions For this purpose they appealed to all the medical men in practice in Swansea and the great majority were very willing to take part in the movement. Only a few hesitated In May, 1902, sufficient propaganda work had been done and the initiators ventured to summon a general meeting This meeting elected a committee which was to frame rules and generally to pave the way for the formation of a society The committee met several times and then convoked another general meeting which was held at the Swansea Hospital on June 3rd Of the 50 practitioners invited 22 were present minutes were taken, and from that date the union of the Swansea medical men may be said to have come into existence Indeed, it was then formally proposed by Mr A. Lloyd Jones and seconded by Mr Jabez Thomas —

> That the practitioners of Swansea and district be invited hereby to form themselves into an association for the purpose of raising the standard of contract practice and that such association be called the Medical Practitioners' Association of Swansea and District

This was carried and then Dr T D Griffiths was elected president and Mr Couch and Dr John D Davies were elected secretaries, together with a committee of ten Their first business was to call on all the medical practitioners who had not yet replied to the circulars sent to them Following quickly upon this action another general meeting was convoked at the hospital on June 10th and this time 28 practitioners were present. Vice presidents and other officers were appointed a temporary subscription of 5*s* per member was fixed upon, and the committee was instructed to study at once the question of a minimum rate of remuneration for contract work. This committee met on June 12th and 16th and yet another general meeting was convoked for June 20th On this latter occasion the rules with some slight alterations, were finally adopted It was also decided to select a solicitor who should be consulted in regard to the bond or pledge which it was proposed to impose on all the members. This was done, and the following is the text of the pledge which has now been signed by 55 medical men of Swansea and neighbourhood —

> We the undersigned members of the medical profession practising in Swansea and district pledge ourselves honourably to adhere to the following rules and regulations adopted at a general meeting of the Swansea and District Medical Practitioners' Association held on June 20th 1902, and refuse to recognise in any way any medical man who acts in opposition to any of these rules and resolutions

The following are the most important of these rules and it will be seen that they are so framed as to apply to the struggle waged in regard to contract work —

> 8. That in the event of any member being given notice to terminate his engagement by any club or works the grounds for complaint will at the request of such member be considered by the association, and if in the opinion of a majority of two-thirds of the meeting the grounds for complaint be unjust or frivolous the member will be supported by the association to the extent that no member may become a candidate for such a position
>
> 9 If any member applies for an increase (above the minimum) from any club or works such member shall, before making such application, bring the matter before the association and if approved, the member will be supported to the same extent as in Rule No 8
>
> 10 In the case of any medical man coming into the district or any medical man at present in the district accepting any appointment contrary to the rules of this association no member may meet the said medical man in consultation, or act as or meet his deputy in consultation
>
> 11 That any member of this association employing an assistant or entering into partnership with any other medical man shall make it a condition of appointment or partnership that the assistant or partner shall at once become a member of this association In the case of an assistant there shall be no annual contribution
>
> 12. That in case of any dispute arising between members with regard to the interpretation of these rules the matter shall be referred to the association and the final interpretation shall be decided by a majority of two-thirds of its members

Having regard to these principles and rules the association did not lose a moment but at once proceeded to take action. The committee met on July 1st and agreed that a demand for an increase should be made, beginning with the workmen's medical aid funds organised at the different works There are at Swansea numerous works for the extraction of metals such as copper, silver, and iron from ore, and for the manufacture of steel, of tin plates, of jointless steel tubes, &c From time immemorial a medical attendant has been appointed to these works, and formerly he used to be selected by the employer Of late years, however, the workmen have maintained that they should themselves dispose of the money which they subscribe and should select their own medical attendant. Therefore the employer now only deducts from the wages the sum agreed upon, and, in fact, acts as a collector for the men The men employed at the same works agree to pay 8*d* or 1*s* per month for medical aid purposes. This sum is handed over to the medical man whom they have selected without, as a rule, any commission being charged for the trouble of collecting A sub-committee met on July 3rd and 8th to draft the text of the demand of the medical men, when an incident occurred which created an interlude but gave the members of the profession their first opportunity of testing the efficacy and advantage of organisation.

An emergency general meeting of the association had to be convoked on July 14th to consider a circular sent by the poor law guardians to each medical practitioner in the town. There was at that time a small pox scare and the guardians asked each practitioner whether he was willing to undertake house to-house vaccination in his district for 2*s*. 6*d* per case. It was felt that the medical men should not be left to answer individually this application, that this was a case for joint action and that all should agree and insist upon the same terms. This impression was confirmed by the result, for at the meeting a motion was carried appointing a deputation to wait upon the vaccination sub-committee of the guardians and to explain that the Swansea and District Medical Practitioners' Association was anxious to afford every assistance to the guardians in their endeavours to stamp out small pox and approved of the proposition of the guardians to organise a house to house visitation for the purpose of revaccination. The association was glad to approve the undertaking of this work by its members at the remuneration offered by the guardians provided that no subsequent visit for inspection was required and that the lymph was supplied or paid for by the guardians. Otherwise the association would consider that the work should be paid for at rates not lower than those which the Local Government Board had formulated as a minimum. The association further recommended that the house of every medical practitioner willing to undertake such work should temporarily and during the emergency be converted into a public vaccination station. The guardians, in reply, agreed to supply the lymph and to pay 2*s* 6*d* for vaccinations at the patient's home. The arm was to be inspected subsequently at the vaccinator's surgery If the vaccination was performed at the surgery then the vaccinator was to supply his own lymph. Thus it will be seen that on the whole a satisfactory arrangement was concluded. It is true that later someone discovered that it was quite illegal, but this does not seem to matter, for while it lasted the arrangement worked satisfactorily for all the parties concerned.

While this was proceeding the main work of the Swansea and District Medical Practitioners' Association was being pushed forward with the rapidity and energy which have distinguished the proceedings throughout. Rarely has an association of this sort held so many meetings in such close succession and organised itself into a fighting machine so rapidly When the next general meeting was held on August 15th the demand had been forwarded to all the medical aid associations formed in connexion with the different works of the town, and now it was decided that a similar letter should be sent to the different clubs or friendly societies. This letter took the form of a sort of circular and was forthwith forwarded to 76 courts, lodges, tents, branches, &c., of the friendly societies. It at once disclosed what is the special grievance at Swansea. As a rule the families are not included in the membership of friendly societies or clubs. If contract work is accepted for the wife and children of members—and this has been strenuously resisted in many localities—then a separate payment is required for the wife and each of the children. As a rule, the general charge is 1*d* a week for the man and the same for his wife, while the children up to the age of 14 years are paid for at the rate of ½*d* a week. Should, however the family be so large that the total sum would exceed 6*d* per week not more than 6*d* is charged. A totally different system obtains at Swansea, and this not only with regard to the friendly societies but also with respect to the medical aid associations formed by the employés of the different works. The members all pay the same sum whether married or not and if they have families the members of the families consider themselves entitled to receive gratuitous medical attendance. Unless it be urged the bachelors pay for them nothing is paid, and yet they all receive medical advice, medicine, and care. It is only when a confinement occurs that a special payment is made for the wives of members and then this is but 10*s.* 6*d* In such extraordinary circumstances it would be thought that the men must pay a very large sum indeed if their families, however numerous, are attended without any extra charge. But this is not the case. Some friendly societies did not pay more than 4*s* 6*d* a year others 6*s*, and others 8*s.*, but 6*s* 6*d* was considered a fair average 1*d* per week each for husband and wife makes 8*s.* 8*d* per annum and ½*d* for the children makes 2*s* 2*d* more per child, but here entire families, however numerous, only paid on an average 6*s* 6*d* These most unfair conditions were instituted 35 or more years ago, and up to the present time they had not been altered. The Swansea and District Medical Practitioners Association in some of its circulars points out that formerly unqualified assistants could be obtained for from £60 to £80 a year and qualified assistants for from £100 to £120 Now none but qualified assistants can be employed and they must be paid from £200 to £250 Then it estimates the cost of qualification at £1000 instead of £500 and the time as six instead of three years as formerly While the expenses of a medical education, of medical practice, and of medicines and dressings have so much increased and thus reduced the profits a medical man may hope to realise, the wages of the working classes at Swansea have increased considerably The circulars also give details in regard to the larger payments made in other towns.

A question of tactics now presented itself. Dr Davies and one or two others addressed themselves early in the history of this movement to the medical aid organisations of the works to which they were attached and succeeded in obtaining an increase from the 8*s* or 10*s* which they had been receiving to 13*s* per family per annum. It was thought that such individual successes would serve as a precedent, yet others making similar applications were refused. Then the association applied on behalf of all the practitioners to all the medical aid organisations at the works and to all the friendly societies. Now the question of tactics is whether it would have occasioned less feeling if each medical practitioner had conducted his own case. A single lodge could not import a medical officer from the outside, but this collective appeal on the part of their medical officers was the means of eliciting a collective reply and collective resistance. Then, after all the medical men had been united very recently and in great haste. The bond drawn up between them had had no time to be tested and no one could tell what was its strength As a matter of fact, a few weak links were discovered which still further encouraged the friendly and other societies to resist the demands of the medical profession, and they did not fail to bring forth the old threat which has done service in so many places of amalgamating all the societies so as to start a medical institute with their own medical men and thus to be independent of all the medical practitioners of the town. However, a great deal was done to clear the air by the acceptance on both sides of a proposal to hold a joint meeting and ten medical men were appointed to meet ten delegates of the friendly societies. This meeting occurred on Nov 12th last and both sides had ample opportunity to make the best of their case. It was a means of throwing light on the one sided view that is often taken. For instance, one workman argued that if the fee were raised many members would leave the friendly societies, and that these would be the most healthy men, the men who gave the least trouble either to the society or to its medical officer, and therefore he did not see the use of paying more Some men had left two years ago when the subscriptions were raised and said that they did not want sick allowances As for the proposal to raise the charge for midwifery to £1 1*s*, half that sum was quite enough, for at such moments workmen had many other extra expenses to meet. It will be seen that in this not a thought is given to the other side—namely, the needs of the medical attendants. In regard to midwifery it is forgotten that in easy cases the medical officer is not sent for at all. It is only in difficult cases that his assistance is requested and then there is more than usual trouble and much time and many visits have to be devoted to the patient. Therefore a fee of 10*s* 6*d* is absolutely inadequate. As for men leaving the friendly societies this is decidedly advantageous to the medical practitioners, because when they are ill they pay full fees Thus what the workman qualifies as unfortunate is considered fortunate by the medical practitioner and it follows that such divergence of interests requires careful handling and a thorough knowledge of both points of view if reconciliation is to be rendered possible.

The workmen also argue that in regard to the increased cost of living this affects them equally Here there is a misunderstanding The chief increase in the cost of living is in rent, rates, and taxes, and in this the workman suffers as much as, and in regard to rent, at least in large towns, even more than, the medical men. But as a whole, with the great reduction in the cost of provisions and clothes, living is cheaper now than it was 30 or 50 years ago. What has increased in cost is the especial outlay that a medical man has to incur so as to obtain his qualification to practise, and to purchase drugs, instruments, &c To put workmen in the same position it would be necessary to enact a law rendering it illegal to employ any workman in any trade unless he had a diploma to show that he had been through a course of technical training and had passed a qualifying examination. This is actually done in a voluntary manner in regard to plumbers and it might greatly contribute to maintain the industrial supremacy of this country if something of the sort were imposed in many other crafts and industries But as matters now stand a workman when a mere youth actually earns money while he is learning his trade. It is but in a few trades that a period of apprenticeship is imposed By far the best argument on the workman's side is that the rent for working-class tenements or cottages has increased much more in proportion than the rent charged for middle-class villas or houses. At Swansea it is said by the workmen that the cottages for which they paid 3*s* 6*d* rent per week some 30 years ago are now rented at 8*s.* 6*d* It is further argued that medical men by taking long leases of their houses can protect themselves against sudden or constant increase of their rent. Also, it is said that the poor rate at Swansea was 1*s* 6*d* in the pound 20 years ago and is now 2*s* 4*d*

On the other hand, Mr E. Reid has calculated that, according to statements made by the corporation, and at the Lambeth Copper Works and the gas works it appears that during the last 20 years wages have increased for joiners from 33*s* to 38*s* 3*d* per week. The figures are the same for masons but for plumbers the increase is from 27*s* to 38*s* 3*d*. The pay of labourers has risen from 20*s* to 24*s* 9*d* and in the case of the lowest paid labourer of all—namely, the labourer in the copper works—he now receives 18*s.* instead of 15*s* a week. Consequently, the workmen can afford to pay more than they did 20 and 30 years ago. They can afford to pay 7*s.* 6*d* for dog licences and they charter special trains so as to attend football matches held in neighbouring towns, they could therefore afford to pay for medical attendance for their families. It is the question of the families which constitutes the bone of contention at Swansea. For instance, Dr Rhys Davies states that the Robin Hood Lodge of Foresters had a short time ago 288 members but there were 193 wives and 270 children, so though there were only 288 members of the society the medical officer had to attend 751 persons He urged that 751 men would be preferable, for he calculated that three wives gave as much trouble as two husbands and that one child required as much attendance as three men. Therefore he might reckon the 193 women as equal to 289 men and the 270 children as equal to 810 men. Consequently the 288 men with their wives and children gave their medical attendant as much trouble as if the lodge had consisted of 1387 men without families Again, if there were a club consisting of 100 children, another club of 150 women, and a third club of 300 men, it would not matter to a medical man which club he took if the pay were the same for each. Mr Reid had calculated that he has given to the members of the Robin Hood Lodge close upon 4000 consultations in the year or 13 consultations for every working day of the year, and this has brought him in 4¾*d* per consultation. For this paltry sum he had to give his time and the drugs and to pay his tram fares and other working expenses Mr Couch has also made calculations and found that when he was receiving on an average 6*s* a year from members of friendly societies for attending them and their families this did not amount to more than 3*d* per consultation and he had to give medicine for that sum He consequently had thrown up all societies that paid less than 7*s* a year Then there is a Provident Dispensary at Swansea and this is to some extent a charity and is partly supported by voluntary contributions, nevertheless, the subscribers pay 1*d* per head for all the members up to 14*s* a year per family, so that this charity is better than the friendly societies which boast of their independence. Consequently the first demand made was that there should be a considerable increase in the amount of the subscriptions so as to cover the cost of attending the families of the members

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Licensing Question

AT the opening of the licensing sessions for Manchester on Feb 6th Mr T T Shann, chairman of the licensing committee, made some interesting observations on the New Licensing Act and on the position of Manchester as compared with some other large towns In 1901 there were 484 licensed victuallers, 1695 beer licences (on), and 744 others (off), making a total of 2923. Since then some further licences have been granted and now there are 2941 to a population of 543,872, so that there is one licensed house to 184 92 men, women, and children Thus "Manchester occupies a most unenviable position, both as regards drinking facilities and intemperance, as compared with other large cities and towns" It stands at the head of a list showing the number of licensed houses, population, and proportion of inhabitants to each licensed house in all the cities and towns in England with over 200,000 inhabitants It has the lowest number of people to each licensed house and possesses several hundred more licensed houses than any other town in the list. Sheffield comes next with one licensed house to 220 95 people Nor does Salford lag far behind, for its proportion is 1 to 222 30 Seaports are proverbial for drinking facilities, but Manchester surpasses in this respect Bristol, Hull, Newcastle-on Tyne, and Liverpool Indeed, Liverpool offers fewer drinking facilities than any in the list except Leeds and West Ham, where the proportion of licensed houses to inhabitants is respectively 1 to 362 91 and 1 to 777 20, which latter stands in marked contrast to Manchester with its proportion of 1 to 184 92. A very large number of the licensed houses are beerhouses, where the sanitary and domestic arrangements are often most unsatisfactory, drinking frequently taking place in the private rooms Mr Shann stated that the facilities for drinking were too great in Manchester as shown by the proportion of licensed houses to population and also by the fact that "the convictions for drunkenness in Manchester are almost double the number per 1000 inhabitants of any other large town." This unenviable state of things is to be altered by a gradual reduction of licences, but with regard to some classes of houses there are certain difficulties. A reduction has already been made of about 11 licences. There is no making people sober, it is said, by Act of Parliament, but it is no less true that with many men the sight of a beerhouse produces a great thirst.

Waterworks for Stockport

The Stockport corporation has a large scheme in hand and is proceeding with the operations for obtaining a supply of water from Kinder Scout. The sources of the supply, according to the report of Dr C Porter, the former medical officer of health, were not ideally perfect, and it will be a great boon to have a supply above suspicion even if it is to cost, as is estimated, nearly a million of money

More Accommodation for Small-pox

At the last meeting of the Manchester city council held on Feb 4th Alderman McDougall said there were 51 patients in the hospital and there was accommodation for 100, which would soon be required if the small pox cases increased as they had done during the previous week The committee therefore, proposed to provide, at a cost of £1500, another ward for 40 patients, and if necessary a second one for 40 more also at a cost of £1500 He stated that out of 49 cases received at Clayton there had been two deaths—one of a child two weeks old and in the other case the disease was complicated with other ailments. In the meantime the number of cases steadily increases. Four were reported yesterday, one from a lodging house and three from the Crumpsall workhouse. Since the end of September last over 100 cases have occurred in Manchester At Eccles yesterday a man was charged with exposing himself while suffering from small pox and failing to notify his case. He travelled from the borough of Eccles to a brick croft in Salford and returned, and his friends and relatives also visited him while the eruption was out. Two cases were removed to hospital yesterday in Oldham. It is said to be impossible to know how many cases there are now, as a policy of secrecy is observed, the health committee having given instructions—so it is stated—to its officials to afford no information to the representatives of the press. What is to be gained by this attempt at concealment one cannot tell Publicity would be less likely to cause panic than concealment, on the principle of *omne ignotum*, &c

Death of Canon Henn.

By the death of Canon Henn, which took place last week at Deganwy the Manchester hospitals have lost a friend who more than 30 years ago did a great work on their behalf. In the year 1870 he organised the Hospital Sunday collections and as long as he was in Manchester he performed assiduously the duties of honorary secretary of the Hospital Sunday and Saturday movement His services in connexion with this work were acknowledged in 1874 by the presentation of a public testimonial which took the form of a purse of money and a silver salver He was consulted and accepted as a guide in the establishment of similar collections in most large towns and even so far away as Melbourne. Up to 1899 about £225 000 were handed over to the medical charities of Manchester from this source Canon Henn broke down in health some years since and in 1900 he was compelled to give up his active work. From that time till his death at the age of 72 he lived at Deganwy, near Conway Till his health failed he was an energetic, hard working man and his zeal in the cause of the medical charities was only a part of a very full life given to his own calling and to that of education

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

Royal Association for Incurables, Edinburgh

THE annual meeting of the Royal Association for Incurables, Edinburgh was held on Feb 5th in the Longmore Hospital Dr Joseph Bell presiding The report of the committee of management for the year 1902 stated that in April last the association had sanctioned a petition by the committee to His Majesty praying that the association might be incorporated under a Royal charter They had every reason to believe that Royal assent to this would be granted in the course of this year The committee also reported the receipt of a sum of £21,000 from the trustees of the late Miss Brown of Lanfine. By the terms of the will the money was to be utilised as follows the sum of £6000 to be expended in the provision of a cottage home in the county for incurable cases of consumption the sum of £14,000 to be held in trust, the interest derived therefrom to be annually devoted to the maintenance of the patients resident in the above home, and the sum of £1000 to be held in trust, the interest thereof to be applied to the outdoor fund of the association The committee reported that it had selected a site which it believed would be approved by the association It was at present in treaty for its purchase The committee, while congratulating the association on this munificent recognition of the value of its work, pointed out that the endowment provided for this new home must only be looked on as the nucleus of an annual revenue, the greater part of which must be obtained from annual subscriptions. The committee hoped to commence building early in 1903. The number of applications for admission to the Longmore Hospital during 1902 had been 259 The number of urgent cases had been far in excess of the available accommodation, with the result that 31 cases had died before they could be admitted and many others had become too ill to move The total number of beds and cots was 150 The total number of patients in the hospital on Dec 31st, 1902 was 69 males and 81 females. The daily average number of patients in the hospital during the year was 143. The legacies during the year, including Miss Brown's bequest, amounted to £28 537 as against £5020 in 1901. The donations amounted to £244 as against £141 in 1901. The ordinary subscriptions amounted to only £1460 7*s.* 5*d* For some years past the ordinary subscriptions had been decreasing The expenditure of the hospital had largely increased in recent years as a result of the increased number of patients, so that now the ordinary expenditure exceeded the ordinary income by something like £2000 per annum. The committee therefore appealed earnestly to all interested in the hospital to secure an increase in the annual subscriptions to the institution, which was the only one of its kind in the south-eastern district of Scotland. The chairman, in moving the adoption of the report, remarked that he was the last survivor in the service of the hospital of the men who nearly 30 years ago started that institution. The other gentlemen who had been associated with him then had all either gone or had left the service of the hospital. He had had the honour of being on the staff of the hospital and on its directorate from the beginning That was his only excuse for his being there. Dr Bell then referred to the various stages in the history of the hospital a history of which, he said, they had no reason to be ashamed. The income from subscriptions, however, had not grown proportionally with the hospital, but had instead shown a falling off. It was scarcely credible, and certainly not creditable, that in 1882 with 50 beds the subscriptions amounted to £2100 while with 150 beds the subscriptions had fallen to considerably less than that sum. Dr Bell then referred to the two classes of patients in the hospital—the incurable cases who, notwithstanding lived for a considerable time, and the more acute and incurable cases, mainly tuberculous and malignant. Although it was a hospital for incurables they nevertheless managed to cure some patients and a cure was very cheering to the other patients as well as to the nurses. One of their incurables was now driving a milk-cart and another had been a tramway conductor for nine years The oldest inhabitant of the institution had been admitted for paralysis 21 years ago while another patient would complete her 21 years in six months' time.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Rotunda Hospital, Dublin

ON Feb 9th a large audience assembled at the Rotunda Hospital to witness the presentation to the hospital by Dr W J Smyly of a portrait of Miss Hampson, first lady superintendent of the institution. Sir Percy Grace Bart D L J.P, occupied the chair Mr O Brien Furlong, K.C, C B, one of the vice-presidents of the hospital, accepted the portrait on behalf of the board

Small-pox in Dublin

At the meeting of the North Dublin rural district council held on Feb. 4th the chairman called attention to the fact that a case of small pox had occurred in Church-street where many tenement houses were occupied by tramps who came and went constantly Mr Edgar Flinn, medical inspector under the Local Government Board, said that he attended that meeting in order to refer to the matter With regard to vaccination the Local Government Board desired him to state that the guardians should proceed against the numerous defaulters. Within the last month Mr O'Neill the clerk, had sent in a return from which it appeared that 70 or 80 people had recently left the locality not vaccinated and might be moving about from one part of the city to another It was a very serious matter and he thought that the board should require the medical officers to furnish a monthly return in order that defaulters might be traced. That course was decided upon. In reference to the isolation hospital question the medical inspector stated that the present arrangement was that the submarine station near the Pigeon House Fort would be utilised for any cases that might occur and that it was hoped the public health committee would have it ready for the reception of patients within a week or ten days In the meanwhile the state of things seems ominous for in addition to the three patients with small pox admitted to the Hardwicke Hospital another case from one of the large institutions of Dublin was reported on Feb. 10th as having been admitted to the same institution

The Royal University of Ireland

At a meeting of the Senate of the Royal University held on Feb. 6th the following appointments were made in the medical faculty for the year —Medical Fellows Dr Ambrose Birmingham Dr Joseph P Pye, Dr Johnson Symington, Dr. John J Charles, Dr D J Coffey, Dr John I. Lynham, Mr John S McArdle, and Dr Charles Y Pearson. Fellow in natural science Dr M. Hartog Examiners in natural science, Dr Michael Curran, Mr Gregg, and Mr Wilson, in medicine, Dr James A. Lindsay and Dr Joseph F O Carroll, in pathology Dr Edmund J M'Weeney and Professor J Lorrain Smith, in midwifery, Professor John W Byers and Dr Alfred J Smith, in medical jurisprudence, Mr Antony Roche and Dr Patrick T O Sullivan, in materia medica, Dr Martin Dempsey and Sir William Whitla, in ophthalmic surgery, Dr Arthur W Sandford and Mr Louis Werner, in physiology, Dr T H Milroy, in sanitary science, Sir Charles A. Cameron, in mental diseases Mr Conolly Norman and Dr George Revington. Extern examiners in surgery, Mr Charles Stonham, C M.G, in midwifery, Dr Henry Jellett, in pathology Dr. A. C O Sullivan, and in ophthalmology, Dr William G Sym

The Belfast Asylum

From the memorandum of inspection by Sir G P O Farrell, M.D Dub, laid before the board of management at a meeting held on Feb. 9th, I find that it is stated that nothing has as yet been done to provide suitable and sufficient hospital accommodation for cases needing special treatment owing to their mental or physical state, further the inspector protests against the new infectious diseases hospital being so close to the Purdysburn Asylum, especially the small pox block. The English Local Government Board requires that a small pox hospital should not, among other things be within half a mile, measured from boundary to boundary, of an institution such as at Purdysburn, where there will be a population in excess of 600 Now the small pox huts which have been erected at Purdysburn are within 285 yards of the asylum. The asylum is much overcrowded. As matters now stand there are 741 inmates at Grosvenor road, while there is a normal accommodation for only 440 It is evident that the asylum committee will have to create further accommodation at Purdysburn. The administration of the asylum by Dr W Graham (resident medical superintendent) is most favourably commented on by the inspector

PARIS

(FROM OUR OWN CORRESPONDENT)

The Investigation of Microbes in Effused Fluids

AT the meeting of the Academy of Medicine held on Feb 3rd M. Jousset gave an account of a very original method for the investigation and detection of microbes in effused fluids—as, for instance, in pleurisy hydrarthrosis, and hydrocele. Hitherto microbes in these fluids have been difficult to detect and M. Jousset has devised the following method He collects some of the fluid and allows it to coagulate, during which process the microbes are imprisoned in the meshes of the clot The clot is then artificially digested and the resulting solution is centrifugated. M Jousset has been able by this method to demonstrate the bacillus of Koch in 24 out of 25 cases of pleurisy and also in certain cases of ascites which had been attributed to hepatic cirrhosis.

Tuberculosis in the French Army

M. Lemoine, Professor at Val de Grâce, basing his facts on an observation of 3000 cases, has shown that of soldiers reported as tuberculous after having joined their regiments 69 per cent had a history of tuberculosis previously to their joining their corps. They did not, therefore, contract their tuberculosis in the army and he draws the conclusion that greater strictness should be exercised at the time of enrolment.

Infant Life Protection

At a recent meeting of the Academy of Medicine M Porak read the report of the committee on the hygiene of infancy This report was at once an interesting commentary on the Loi Roussel and an inquiry into its method of working and its results. The efficacy of this Loi Roussel is to-day clearly shown. Everything goes to prove the correctness of this statement and of the generally expressed opinion of the medical profession. For instance, the infantile mortality in those departments which receive nurse children from Paris has decreased within the last 20 years, while within the last 50 years the mortality in foundling hospitals (*Service des Enfants Assistés*) has fallen from 60 per cent. to 21 per cent. All the same, within the period of from the end of the first month of life to the end of the first year the mortality among nurse children is still double that of the general mortality among infants of the same age. It would appear, then, that certain improvements might be made in the Loi Roussel, as for instance in the way of assuring gratuitous medical attendance for nurse-children and legal assistance for nurses, by reorganising medical inspection, by extending the provisions of the law to the children of nurses who have taken a place and who have handed over their own children to the care of a neighbour or to someone who takes them without payment, and, finally by regulating the delivery of certificates and the keeping of the registers of service. The committee was not unanimous as to the interpretation and scope of clause 8 of the Loi Roussel, which clause imposes upon nurses who have taken a place as wet nurse that they should undertake to suckle the child for seven months The committee says that an inquiry should be held into the advantages or disadvantages of this enactment. Recent statistics furnished by the Minister of the Interior show that 65 per cent. of the women confined in Paris cannot suckle their children, either on account of poverty, or because they have no milk, or for other reasons.

The Transmission of Syphilis made a Penal Offence

The tribunal of the Seine has just delivered an important judgment. By this judgment the transmission of syphilis by persons knowing themselves to be affected, even though they do not wish to transmit the disease, comes under the category of injury inflicted on another and gives the victim the right to an indemnity Already the law has condemned parents whose child infects a nurse with syphilis, but the direct transmission of syphilis through sexual relations considered as a wound for which an indemnity is payable comes under the purview of French law for the first time. The case in question was that of a man suffering from syphilis who had sexual intercourse with a girl, aged 16 years, who contracted the disease from him. She had previously been quite well and a virgin. The court condemned the man to pay 12,000 francs damages.

EGYPT

(FROM OUR OWN CORRESPONDENT)

Cholera and the Tourist Season

THERE is now no cholera in Egypt and it has been entirely absent for several weeks. I am obliged to mention this fact because the European papers have lately published a telegram stating that the French Government has now forbidden the annual pilgrimage to Mecca from Tunis because of the cholera in Egypt. This is obviously unnecessary, for most of the Tunisian pilgrims arrive at Port Said by sea and then go on to Jaffa through the Suez Canal. It is only a small proportion of them who laboriously walk along the North African coast or who elect to land from the sea at Alexandria. But we often notice that Egypt pays the penalty of her honest declaration of bulletins of any epidemic disease by being accused of suffering from that disease when it is no longer present. The season began badly and even now there are not so many visitors here as there usually are at the end of January But as some of the hotels are already full no one has a right to grumble The *Commonwealth*, belonging to the Dominion Line, has lately arrived with 100 Americans from Boston *via* Gibraltar, Genoa, and Naples

Dysentery

At the Medical Congress here Dr Kartulis of Alexandria was chosen to open a discussion on Dysentery with reference, of course, to its connexion with abscess of the liver He is a well known exponent of the amœbic theory and his experiments by injecting pus from a liver abscess into the rectum of healthy cats and thereby producing dysentery are recorded in all text-books. He still believes that amœbæ are the only cause of tropical dysentery, that tropical abscess of the liver is three times out of four caused by amœbic dysentery, and that non dysenteric abscess of the liver met with in the tropics is chiefly caused by intestinal lesions, a few exceptional cases only being pyæmic, also that alcohol and malaria produce hepatitis and thus predispose to abscess without being the direct cause Dr Kartulis quoted 1860 cases of dysentery reported from India by different observers, of which 420 had abscess of the liver, and he contrasted with them 1896 cases of epidemic dysentery reported from Europe, among which there were only 28 cases of abscess of the liver. His own figures, collected over many years, give 164 cases of abscess of which 95 had a previous history of dysentery, 17 others were alcoholic, 25 had some unknown cause two were caused by wounds of the liver, and the remainder had a history of vague enteritis some of which may have been dysenteric He pointed out that nobody knows yet the nature of pilgrim diarrhœa or of that of Indo-China, but that otherwise the dysentery of the world seemed to be divided into the tropical or amœbic form and into the epidemic variety characterised by the presence of the bacillus discovered in 1897 in Japan by Shiga and confirmed later by Kruse in Germany Dr Kartulis firmly believes that suppuration of the liver is produced not by the amœbæ, but by pyogenic microbes such as the staphylococcus albus or the staphylococcus aureus It is, of course, impossible to prevent as yet the occurrence of dysentery, but it seems possible to prevent a dysenteric case from developing later into hepatic abscess In hospital and private practice numerous instances are seen of treated dysentery not being followed in after years by hepatic abscess, and, on the other hand, cases of hepatic abscess that are met with are almost always due to dysentery neglected or improperly treated. Dr Kartulis denounces the so-called specific treatment by ipecacuanha or calomel and has but scanty faith in aperients He maintains that dysentery is a local disease and ought therefore to be treated locally Directly he is called to a patient he prescribes two tepid enemata of a watery solution of tannin (1 in 200) and this he believes to be the essential treatment for amœbic dysentery and to prevent the formation of hepatic abscess. Dr Legrand (Alexandria) read a paper on the merits of Kosam which he has used in 30 cases of dysentery during the last two years. It is a seed coming from a shrub of the family of Simarubaceæ discovered by Dr Mougeot, the prison medical officer at Saigon It must be given in large doses, is equally useful for the acute and chronic form, but is of no value for diarrhœa which is not truly dysenteric. In addition to kosam by the mouth enemata of antipyrin and laudanum are also given to overcome the tenesmus. Dr Métin (Director of the Pasteur Institute at Saigon) claimed to have discovered that the specific cause of dysentery in Cochin China is a cocco-bacillus which resembles most the microbe of plague. It is not reproduced by spores, a temperature of 140° F kills it in two hours, while at boiling point it dies in a few minutes , also antiseptics kill it with ease, and per chloride of mercury (1 in 2000) stops its growth. Rabbits are killed by it in 12 or 18 hours, their axillary and inguinal glands are swollen, and in the peritoneum and pericardium is found bloody serum which is practically a pure culture of the cocco-bacillus. The animal's intestines are red and distended by gas and by bloody fluid mixed with normal fæces. But there is apparently no ulceration of the intestines. The lungs and spleen are apparently healthy, the liver is hyperæmic but of normal size, while all the organs, specially the liver, contain hundreds of cocco-bacilli. Dr Métin has never found his bacillus in the air or in the soil, but he has often discovered it in the water, where it is most easily found during the dysentery season He ended his paper by stating that he had sent to Dr Roux of the Pasteur Institute in Paris cultures of the bacillus which he claims to have discovered in March, 1901 Professor Chantemesse (Paris) stated that in 1888 he and Dr Widal, while performing necropsies upon soldiers who had returned from Tonkin, had discovered a bacillus which he had now been able to identify with that now known by the name of Shiga's Dr Belleli (Port Said) read a paper recommending large enemata as the best treatment of dysentery The injection he prefers in acute dysentery is two pints of water containing from 25 to 40 drops of carbolic acid, while in chronic cases he uses the same injection with the addition of tannic acid and laudanum. Dr Pressat (Ismailia) also said that he believed chiefly in treatment by enemata and he recommended large injections with a solution of chloral of from 5 to 10 per 1000 He stated that this was sufficient to bring about recovery provided that the diet was carefully limited and he had never seen any symptoms of chloral poisoning

National Sanatorium Association

THE annual meeting of the board of trustees of the National Sanatorium Association was held recently in Toronto, with the Vice-President, Sir William Meredith, Chief Justice of Ontario in the chair The annual report of the Muskoka Cottage Sanatorium was submitted by the physician in charge, Dr J H. Elliott. It showed that during the five years history of the institution 612 cases of consumption had been treated and that during the past official year 85 per cent. of the cases treated had been cured or the disease arrested. 90 cases were treated at the Free Hospital for Consumptives, Muskoka, during the first five months of its existence. Of the 90 patients 50 came from Toronto and the balance from other parts of the province of Ontario and the Dominion. The announcement was made by the secretary of the association that a fine site for a third institution was already purchased near Toronto and that a citizen of this city had promised to contribute $25,000 towards the erection of the buildings. The association also has in contemplation the establishing of a fourth sanatorium in the near future on the Pacific coast.

Annual Report of the Sick Children's Hospital, Toronto

The twenty seventh annual report of the Sick Children's Hospital, Toronto, shows that during the past official year 5373 patients were treated. Of these 749 were in patients and 4624 were out-patients Of the in patients 520 were free patients who were in the hospital 28,131 days, thus showing that 70 per cent of the entire number were unable to pay for hospital treatment There were 128 patients in residence at the beginning of the official year, 621 were received during the year, and 627 were discharged, leaving in the hospital on Sept 30th, the end of the official year, 122 patients The medical report shows that of the in patients 447 were cured and 209 were improved and greatly benefited. There were 471 operations performed during the year The cost of each patient per day was 88 11 cents This hospital was closed to the admission of patients during the year owing to an outbreak of scarlet fever and diphtheria.

Canada's Drink Bill

The annual report of the Canadian Inland Revenue Department shows that during the past official year 3,234 147 proof gallons, as compared with 2 652,708 proof gallons for the previous year, were produced in Canada. The people drank more spirits and beer than in the previous year, the quantity of spirits consumed being 0 796 gallon per head against 0 767 for the previous year Beer is represented by 5 102, as against 4 737 for the previous year, and wine by 0 090 as compared with 0 100 for 1901. The consumption of tobacco was the same as in 1901. The number of cigarettes consumed last year was 134 236,034, as against 121,383,584 in 1901.

Montreal Contagious Diseases Hospital Question

For over three years the city council of Montreal has had before it the question of the erection of a new hospital for cases of infectious and contagious disease. The trouble in failing to arrive at a definite plan for adoption during all that time has been that while certain members were in favour of one hospital there were others who considered that two hospitals, one for the Roman Catholic and one for the Protestant population, were desirable. It seems that a definite plan has at last been decided on. The council has proposed to the Notre Dame Hospital, representing the French element of the city, and to either the General Hospital or the Royal Victoria Hospital, representing the English portion of the population, that it would give $15,000 a year each to these institutions if they would care for the cases of contagious disease arising in the city, the contract to extend over a period of 25 years The board of governors of Notre Dame Hospital has accepted the offer for that institution, and it is understood that one of the two English hospitals will shortly follow suit.

The New Professor of Hygiene at McGill University Montreal.

The annual university lecture of McGill University was delivered on the afternoon of Jan 23rd by Dr T A. Starkey, the newly appointed professor of hygiene, who a few weeks ago came over from London University to succeed the late Dr Wyatt Johnston in the chair of hygiene. Professor Starkey in introducing the subject of his lecture "Hygiene" referred at some length to the work which the late professor had done both outside and in connexion with McGill University He spoke of the research which Dr Johnston had instituted in connexion with bacteria in milk and in water as well as of his work in connexion with medico-legal matters, his work on accident assurance—compensation and adjudication—being invaluable. Professor Starkey considers that social progress, general enlightenment and constitutional freedom have added a great deal to hygienic reform.

The Health of Victoria, British Columbia

The annual report of the medical officer of health of Victoria, British Columbia, shows that during the past 12 months that city has enjoyed good health At no time was there any tendency to an outbreak of any contagious or infectious disease. During the year there were 83 cases of diphtheria, with three deaths and 48 cases of scarlet fever, with no deaths There was only one case of small pox during the year Knowing that bubonic plague is present in San Francisco the medical officer of health of Victoria has taken every precaution to prevent its introduction into Victoria, and in this respect his efforts have been assisted by the strict quarantine system of the Canadian Government. In 1901 the death rate in Victoria was 12·33 per 1000 , last year it decreased to 10 09 per 1000

NEW YORK

(FROM OUR OWN CORRESPONDENT)

An Institution for the Study, Prevention, and Treatment of Tuberculosis in Philadelphia

THE announcement was made some three weeks ago that Mr Henry Phipps of New York intended to establish in Philadelphia an institute for the above purposes. It is proposed to erect buildings in the centre of the city, in the midst of the poor neighbourhood, at a cost of from $200,000 to $300 000 (from £40,000 to £60 000) An endowment of $1,000 000 (£200,000) will also be provided, yielding an annual income of $40,000 (£8000) The institute will be known as the Phipps Institute and is intended to be a centre for the distribution of knowledge concerning tuberculosis, with the object of checking its spread. There will be an administration building containing a Finsen light department, a hydro therapeutic department, with baths and electric appliances, and also pavilions with a capacity of 100 beds for the treatment of advanced cases of pulmonary tuberculosis There will be also a dispensary for the treatment of "walking cases" from which assistance will be given to poor tuberculous patients in their own homes and a general supervision will be kept over them for the purpose of instructing them in methods of preventing the spread of the disease It was intended to begin the work at once in a temporary building rented for the purpose, but an obstacle has arisen in a Pennsylvania law which restricts the erection of hospitals in certain parts of any city in that State. If the Bill for the repeal of the law is defeated in the Legislature the institution will be established in a poor district of New York city

The New Maternity Hospital in New York City

The Society of the Lying in Hospital of New York, which was presented with a magnificent new building some months ago by Mr J Pierpont Morgan, has recently issued its annual report. It is stated in this report that the hospital was opened for the admission of patients eight months ago, since which time 1278 women have applied for indoor treatment. Owing however, to lack of funds only one ward of 62 beds has been available for this purpose The building contains 186 beds, so that just one third of them are being used New York is badly supplied with accommodation for poor pregnant women, the total capacity of such institutions in the city being less than 600 beds For the year ending Sept 30th, 1902, the number of births in the borough of Manhattan, according to the official returns of the Health Department, amounted to 51,665, showing that on an average one child was born every 10 minutes The statistics of the society during the past year showed a large increase in the number of cases over those attended in the course of the preceding year, the applicants being 4815, an increase of 1058 Of this number 878 were admitted into the hospital The total amount of money expended was $78,659 (£15 731) The report calls attention to the fact that the number of cases treated in the out-door departments of the society was less than a year ago while the number of applicants was very much larger The report lays special stress upon the need of a sufficient endowment to enable the new hospital to perform a vast work of good among the destitute poor of New York city

Obituary.

JOHN WEBB WATKINS, M.D EDIN, M R.C S ENG

DR. WATKINS of Kirkby, Newton le Willows, Lancashire, who died somewhat unexpectedly on Jan 30th, had at various times occupied important positions. He was born at Towcester, Northamptonshire, in May, 1833, and came of a medical family, his father, Mr Thomas Watkins, and his grandfather, Mr Timothy Watkins, having been surgeons practising in that place. He studied medicine at University College, London, and at Edinburgh University, becoming qualified as M R.C S Eng in 1855 and graduating as M D at Edinburgh in 1856 In the early part of his career, we have been informed, he was a prominent figure in an episode of the first interest in medical history While he was a student at Edinburgh the anæsthetic properties of chloroform were discovered by Sir James Simpson, and Dr Watkins, who offered himself for the purpose of the experiment, was the first person to whom he administered it. Dr Watkins took so much interest in the question that he chose Anæsthesia in Natural and Morbid Parturition as the subject of his graduation thesis On entering professional life he at first spent some time in Towcester, assisting his elder brother In 1857 he settled in Newton le Willows and practised there up to the time of his death. He held a variety of appointments, including those of medical officer of health, certifying factory surgeon, medical officer to the post-office, and several others In 1887–88 he was president of the Lancashire and Cheshire Branch of the British Medical Association. He was honorary surgeon to the local volunteer force, attained the rank of surgeon major, and on retiring after being 20 years with the battalion he received the volunteer decoration for long service. He took a great interest in educational and Church work and was for a long period a member of many Liverpool diocesan committees, from which he was selected by the late and present Bishops of Liverpool to be a representative in the House of Laymen in York Dr Watkins was a widower and has left a large family Three of the sons are following their father's profession. The funeral took place at Newton Cemetery on Feb 3rd.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND—At the examination for the Diploma in Public Health the following candidates passed —

W H. Hornibrook, L.R C P & S Irel. J M. Keegan M.A. M B B Ch R.U.I J McLiesh, M.B B Ch, R.U I.; J B. Stephenson M.D Durh.

TRINITY COLLEGE, DUBLIN—At examinations held recently the following candidates were successful —

PREVIOUS MEDICAL EXAMINATION

Anatomy and Institutes of Medicine.—Robert A. Askins, Cecil Scaife, and John B B Whelan

Physics and Chemistry—Henry H. A. Emerson, Joseph C A. Ridgway Joseph E. N Ryan, William E. M. Armstrong, Cyril H. M Comas and John Murdoch.

Botany and Zoology—Thomas P Dowley William M. Johnston, William H. Kennedy Charles Ff Rolleston, and James G M. Moloney

LITERARY INTELLIGENCE—His Majesty the King and His Royal Highness the Prince of Wales have graciously been pleased to accept copies of the first Prize Essay for the Erection of "The King Edward VII Sanatorium" for the Treatment of Tuberculosis, by Arthur Latham M A, M D Oxon, M.A Cantab. assistant physician at St George's Hospital and to the Brompton Hospital for Consumption, in association with A William West, architect. —A new edition of "The Uniform System of Accounts for Hospitals and Institutions," by Sir Henry Burdett, K.C.B, will shortly be issued by the Scientific Press, Limited

BIRMINGHAM GENERAL HOSPITAL.—A rare cause of death occurring from the administration of nitrous oxide gas happened at the above hospital on Jan. 28th to a man, aged 33 years. At the inquest it was stated that the patient had an enlarged gland in his neck which was probably connected with the presence of some bad teeth The gas was administered by the house surgeon from a cylinder in the ordinary way When the dentist had extracted one of three teeth the man became blue and asphyxiated and in spite of prompt treatment he never rallied His chest had been specially examined beforehand and his breathing was stated to have been quite clear. It is not a common result, fortunately, for such an event to occur and the confidence in the use of gas need not be unnecessarily shaken.

BOOKS, ETC, RECEIVED

ASSOCIATION OF AMERICAN PHYSICIANS (Dr Henry Hun, Secretary 149 Washington Avenue, Albany N Y)

Crawshaw – The wife of J H Crawshaw L S.A Lond Midland View, Elsecar of a daughter (still born)

Turner.—On Feb 6th at Plympton House, Plympton, South Devon, the wife of Alfred Turner, M D Edin., of a daughter

MARRIAGE

Marshall—Higginson —On Feb 4th at St. Jude s Church South Kensington by the Rev Salter St. George John Hartley M.A., *vicar of Exton Rutland assisted* by the Rev William Millar M.A., vicar of Tillingham Essex and the Rev Prebendary Eardley Wilmot M A vicar of the parish Thomas Bingham Marshall M R C S , L.R C P of The Limes Tillingham Essex, elder son of the late Thomas Alexander Marshall, to Ruth Forbes, youngest daughter of Arthur Higginson of 46 Penywern road, South Kensington.

DEATHS

Brake.—On Feb 8th, at San Remo Craneswater-park, Southsea, Surgeon General Brake late I M S aged 75

Sharp —On Feb 9th at the Royal Victoria Hospital Hull, Ellen Mary Sharp M.B Lond , House Surgeon to the hospital, aged 28 years

Watkins.—On the 30th Jan. at Kirkby, Newton le-Willows suddenly, John Webb Watkins M D , aged 69

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL MAN THE CORONER AND THE PATHOLOGIST

AT a recent inquest in circumstances which we have already described a censure was passed upon a medical man in his absence the absence having been explained to Mr Troutbeck in a letter which Mr Troutbeck, according to the reports in the press described as impertinent. The writer of the letter Mr Ernest R. Badcock says that this description of his letter may do him professional damage and asks us to publish it that his colleagues may judge of it Here it is —

SIR,—I cannot allow to pass without protest your misguided action towards me with regard to the inquest on the body of the child Harvey

Surely it is of importance in the interests of justice that the medical man who is first called to the case be called at the inquest.

It was a frequent question of your much respected predecessor the late Mr Braxton Hicks And *doctor what do you know of* the character of these people?" How is it possible that a stranger coming in can further the ends of justice in this way however much he may be able to teach the general medical practitioner about his work?

I must apologise for using this paper, *it is the only writing paper* I find available at the moment.

I am, Sir your obedient servant,

ERNEST R BADCOCK.

Mr Coroner Troutbeck Town Hall Wandsworth

We cannot see any impertinence in the above letter Mr Badcock, like ourselves considers Mr Troutbeck's procedures in the matter of medical evidence wrong Mr Badcock was *absent from the inquest* because he did not receive a subpœna and we think that he was quite right to absent *himself for that reason. If medical evidence is* required it should be obtained in the proper way Medical men must not give *medical evidence to a coroner s officer* for him to repeat probably incorrectly and certainly unintelligently to a jury That way leads to failure of justice. Nor should medical men be compelled to attend inquests without a subpœna so as to protect themselves from misrepresentation possibly of a damaging nature We have reason to know that Mr Troutbeck repudiates very strongly the idea that he is acting in opposition to or in a contemptuous way towards the medical profession We hope that he will tell his juries that no medical man *need attend an inquest unless he is properly summoned* and that no imputation rests on his character if he refuses to give medical *evidence save under subpœna.* Mr Badcock has, we think, been treated with distinct hardship

We continue to receive letters similar to the one that follows and we trust that the matter will be brought properly to the attention of the London County Council —

To the Editors of THE LANCET

SIRS —Regarding the innovation in procedure which has been sprung upon the medical profession and the general public by Mr Troutbeck will you allow me to draw attention to the fact that even eminent pathologists are not always able to account for death after opening and *examining a body?* The fullest proof of death from natural causes is afforded by the evidence of the medical attendant concerning the nature and symptoms of the illness as he has observed them before death *plus* the evidence of this same observer or another pathologist assisting him concerning what is found internally and externally after death Neither the one part of evidence nor the other can ever equal the two together A pathologist however eminent he *may* be, should never determine the natural cause of death *before* a jury *if* there has been a medical attendant in the case The latter should determine, being assisted by another pathologist when desirable whose only duty it should be to present *facts* and figures regarding what he finds

This innovation introduced by Mr Troutbeck, is one of very great importance to the medical profession and the general public, for other municipal councils may be induced to advocate the adoption of the same procedure

I am, Sirs yours faithfully

Surbiton Jan 31st 1903.

HAYDN BROWN

EMPLASTRUM BELLADONNÆ (?)

To the Editors of THE LANCET

SIRS —Some months *ago two cases* came to my notice where emplastrum belladonnæ (labeled as such) produced distinct blistering In one case I saw the blister *myself* and I would have said it was due to cantharides. In the other case I saw the pigmented scar and on inquiry I *found* that there had been marked blistering I had the curiosity to inquire who were the makers of the *plasters* and *I found* that both were made by the same firm but sold by different druggists. One of these to whom I mentioned the *matter wrote* to the makers and they replied that strong belladonna plaster sometimes produced blistering I have never seen anything more severe than slight irritation from the application of a belladonna plaster I would like to elicit any information as to whether other practitioners have had a similar experience. A blister 6 × 10 inches is rather an unpleasant result of the application of a belladonna plaster for the relief of pain in the back

I am Sirs yours faithfully,

Jan. 28th, 1903.

B. R

PATENT HYGIENIC UNDERWEAR

WE have received specimens of underclothing invented by a foreign medical man Dr Rasurel *The materials of* which the clothing is made are wool and peat fibre This fibre is very absorbent and possesses antiseptic properties. The clothing is supplied either in the *natural* greyish-brown colour or bleached It makes a warm and singularly light garment even in the thickest qualities. The seams are very carefully turned *so that there are no* rough edges, and from a personal trial we can say that the garments *are comfortable* and that *no shrinking is* apparent at least after one washing although no woollen fabric will stand the manipulations, or rather the machinations of a London washerwoman for long The clothing can be obtained by application to Mr H. Clauzier, 105–107 Wood-street London E C

THE FUNCTIONS OF A PARISH NURSE

WE *have received a circular dealing* with the appointment of a parish nurse for the parish of All Saints, Wyke Regis The nurse is apparently under the control of a benefit nursing club to which the medical adviser is stated to be Dr Moore. Among the rules of the nursing club as given in the circular the first one reads as follows —

The nurse will be qualified to attend *ordinary cases of* illness and confinements but must not attend infectious cases" Other *rules state that there will be no fees for* attendance except in the case of confinements and for the latter a fee of *7s 6d* is paid For *this charge* (says *Rule 4*) the nurse will *confine* the mother and attend her and the baby twice a day for 10 days Whenever necessary the nurse shall call in the doctor at the time of confinement In the case of the wives of labourers and artisans this *doctor s fee* will be paid by the nursing club" With regard to Rule 1 stating that the nurse will be qualified to attend *ordinary cases* of illness we wrote to the secretary to inquire whether or not the nurse had a registrable *medical qualification,* and we received the following answer The nurse attached to the Wyke Regis Benefit Nursing Club has a medical *qualification for nursing* We presume this means that the lady in question holds the certificate of the Obstetrical Society of London, which of course is no qualification of any kind We have no doubt that a parish nurse is a most useful official but we cannot think it right that any persons should be at liberty to apply for her services except with the leave and at the direct instigation of their medical attendant It seems to us that Rule 1—viz. The nurse will be qualified to attend *ordinary* cases of illness —simply means that the nurse is an unqualified medical practitioner and we shall be glad if the committee or the medical adviser to the club will inform us what are considered to be ordinary cases of illness and in what manner the nurse is qualified to attend such cases.

CITRATE OF CAFFEIN

To the Editors of THE LANCET

SIRS —I should be very much obliged if you or any of your readers would refer me to any reliable source of information concerning excessive indulgence in citrate of caffein I wish to ascertain whether the acquirement of a habit of taking this drug has often been met with and what the effects of long continuance of large *doses* are likely to be. With regard to effects can it be responsible directly for (*a*) polyuria, and (*b*) very obstinate *constipation?* And can it of itself lead to pigmentation of the skin? I must apologise for troubling you, but I have been unable to find any accounts on the subject.

I am Sirs yours faithfully

E T

LONGEVITY

IN THE LANCET of Sept 7th (p 343) and *21st* (p 427) *1878* and April 5th 1902 (p 979) reference was made to the case of a man named Michael Solis who in *1878* was *living* in Bogotà, Colombia, South America, and at that time claimed to be 184 years old Evidence, however was *forthcoming* to the effect that his age was in reality not much if at all over 90 A similar story is now being *repeated* the details as given in the *Liverpool Daily Post* of Jan 30th being to the effect that Manuel Del Valle, of Menlo-park, *California* has reached the age of 157 years. The certificate of his birth which he has always had in his possession was signed *by the then chief* magistrate of Zacatecas Mexico and shows that he was born there on Nov 24th 1745 This proof is *supplemented by the records* of the Mexican Customs Service in which he served 20 years while from 1814 to 1845 he *acted as supernumerary* in the *Franciscan* Mission at San Quentin in Lower California, the first mission building erected *on the Pacific coast. In 1845* when he was just 100 years of age, he went with some relatives to what is now San Francisco and has *occupied the house* in which he now lives ever since. He is naturally a dried up specimen of a man scarcely five feet in height and weighs *about* 90 pounds but he is still able to walk about without assistance and goes for a little stroll every day His *eyesight* is considerably impaired but he hears very well Naturally he does not take solid food and all his life he has abstained *from* tobacco and alcohol.

QUICK LUNCHES

To the Editors of THE LANCET

SIRS —Your paragraph recommending physicians to impress upon their patients the wickedness of quick lunching does us a great injustice which we feel sure you will be only too glad to remedy when the facts are put before you The whole matter lies in the misinterpretation of the words quick lunch What we mean by that is lunch quickly served We propose to serve our customers as nearly as humanly possible without waiting In nine-tenths of the restaurants and tea rooms at present in existence a customer has to wait too long for his food and this is a waste of his time which we hope to remedy but we certainly have no wish in any way to dictate as to what time he shall take in eating it. Our customers will be free to take any time they may please in partaking of their meals and we hope to command their custom by quick service cleanliness and the appetising nature of the dishes we expect to place before them Trusting you will give this the same prominence as you did the paragraph in question we remain,

Yours truly

THE BRITISH COFFEE AND QUICK LUNCH SYN LIMITED

Feb 7th 1902 (H ERNEST BLOKETT, Secretary)

THE CASE OF DR RAINSBURY

To the Editors of THE LANCET

SIRS —I am desired by the council of the Midland Medical Union and by Dr Rainsbury to acknowledge the receipt of further donations to the fund raised to assist Dr Rainsbury in discharging the judgment which was given against him at the last Nottingham Assizes and which was deemed to be a great hardship upon him The judgment was for £25 and the costs were taxed at £152 6s 2*d* making together the sum of £177 6s 2*d* Of this members of the profession have generously contributed £77 0s 9*d* I have to express Dr Rainsbury s gratitude to the contributors for their assistance and the thanks of the council for the liberal response which has been given to the appeal

I am Sirs yours faithfully

GEORGE S O ROBKE

Nottingham Feb 9th 1903 Secretary Midland Medical Union

Dr M A. Ruffer Alexandria	1	1	0		£77	0	9

THE PROSTITUTION OF THE POST OFFICE

A CORRESPONDENT writes to us that he is extremely annoyed at receiving a money lender s circular He asks whether any steps can be taken to prevent a repetition of this gross insolence We are afraid that nothing can be done We have on previous occasions referred to the manner in which the post-office distributes money lenders circulars advertisements of quacks and other offensive literature, but apparently nobody—not even the Postmaster General—has any power to put a stop to the annoyance. Our correspondent may consider himself lucky that he does not get worse things than money lenders circulars and in open envelopes or on post-cards

SUGAR IN VEGETABLES

To the Editors of THE LANCET

SIRS,—Would you kindly tell me whether celery the white of asparagus and sea kale are all rich in sugar ?

I am Sirs yours faithfully

Feb 9th 1903 B

*** The following is the proportion of carbohydrates in the vegetables mentioned : asparagus 2 9 per cent sea kale 3 8 per cent sea kale cooked 0·3 per cent celery 3 3 per cent and celery cooked 0 8 per cent.—ED L

ARE YOU REQUIRING SPECTACLES ?

A CORRESPONDENT has sent us a paragraph thus headed extracted from the *Bradford Daily Telegraph* which is an advertisement of a firm of consulting eye specialists and ophthalmic opticians named Forshaw and Co F S M C A testimonial in the shape of a letter from Dr A. Ramage L R C P L R C S Edin is appended which says that it is not surprising that my friend Dr Charles Forshaw should be so singularly successful as an optician " &c. Such a letter from a qualified medical man to people of the class of Forshaw and Co seems to us surprising

QUALIFICATIONS FOR PRESCRIBING

To the Editors of THE LANCET

SIRS —Will you be kind enough to inform me if it is *illegal* in Britain for the possessor of a diploma (M D) from a highly reputable medical college in the United States to prescribe or give away a medicine which contains poison ?

I am, Sirs yours faithfully,

Feb 7th, 1903 OLYMONT

*** It is not illegal for anyone to prescribe or to give away a medicine containing a poison provided that the person so doing does not pretend or imply that he is a registered medical practitioner —ED L

THE TESTIMONIALS TO ODOL.

IN reference to our allusion to a testimonial apparently given by the late Dr Leonard Wilde to the Odol Company the original document has been produced to us There can be no doubt that the testimonial in question was printed in perfectly good faith by the Odol Company who believed that they were right in attributing it to Dr Leonard Wilde In regard to Dr A S Gubb s letter published in our issue of Jan 24th disclaiming the testimonial purporting to be given by him to the merits of odol" we are informed that the words occurred in a compilation made by him from foreign criticisms and that his name was attached to them in error The proprietors of odol" state that they have already apologised to Dr Gubb in a manner that at the time appeared quite satisfactory to that gentleman for their error in affixing his name to the words but they cannot allow the suggestion to remain uncontradicted that the testimonial is a fictitious one

SANATORIUMS FOR TUBERCULOUS CASES

To the Editors of THE LANCET

SIRS,—I have noticed from time to time inquiries in your columns as to what facilities there exist for giving the poorer classes the advantages of the open air treatment for pulmonary tuberculosis. I write to tell you that I and my colleague here Mr J B Chapman, have arranged for the reception of 12 early cases in a house near here where we are prepared to treat them for 17*s* a week per head The patients however must be genuine early cases The 17*s* just cover the cost of board and lodging There is no charge for professional attendance or *drugs &c. (The patients must of course be of the class unable to pay* for treatment at even the cheapest sanatoriums)

I am Sirs yours faithfully

NOEL D BARDSWELL, M D M R C.P Edin. &c.

Mundesley Norfolk Feb 6th 1903

◆

Rusticus —1 Our correspondent will find the answer to his first question in an annotation headed ' Ante-Natal Rigor Mortis " which appears at p 460 of this issue of THE LANCET 2. It is no doubt possible for meconium to be expelled soon after the death of a fœtus either in utero or after birth by peristaltic action of the intestine since such contractions persist for some little time or by the production of increased intra abdominal pressure due to putrefaction Its expulsion is however much more commonly due to pressure on the abdomen of the child alive or dead during birth or to excessive peristaltic action of the bowel at the time of death

Country Practitioner —The community are perfectly right to make a representation to the Local Government Board if they can produce real evidence of jobbery The Local Government Board would certainly consider such a petition but a petition claiming the post for a particular candidate on the ground of his diploma or his residence would not have much weight.

M B Camb has not inclosed his name and address

ERRATA —Dr William Hunter requests us to insert the following with regard to his paper on Pernicious Anæmia which was concluded in THE LANCET of Feb 7th 1. Page 368 column 1 under *Summary* A spontaneous origin without clear etiology is the rule " should read is the exception 2 Page 369 column 2 top paragraph ' the past 25 years, should read ' the past 15 years."

Medical Diary for the ensuing Week.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W)—5 P.M. Dr Robinson Pelvic Pain

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton)—4 P.M. Dr P Kidd Cases of Laryngeal Tuberculosis.

THURSDAY (19th)—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—4 P.M. Clinique. (Surgical.) 5.15 P.M. Mr J J Clarke Tuberculous Disease of the Spine.

POST GRADUATE COLLEGE (West *London* Hospital, Hammersmith road, W)—5 P.M. Mr Baldwin Treatment of Some Injuries and Emergencies.

UNIVERSITY OF LONDON (Physiological Laboratory)—5 P.M. Dr T G Brodie: On the Circulation (Lecture on Advanced Physiology)

CHARING CROSS HOSPITAL.—4 P.M. Dr Murray: *Demonstration of Medical Cases.* (Post Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt Ormond-street, W C)—4 P.M. Mr Collier Demonstration of Selected Cases.

NORTH EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital N)—4 P.M. Clinical Lecture—Mr H. W Carson: Some Remarks on Hernia.

FRIDAY (20th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof C B Ball: Adenoma and Adeno-Carcinoma of the Rectum. (Erasmus Wilson Lecture)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C.)—4 P.M. Mr E. Clarke: Clinique. (Eye.) 5.15 P.M. Dr H. L Barnard: Acute Appendicitis.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W)—5 P.M. Dr Reece: Shellfish Culture in Relation to Disease.

UNIVERSITY OF LONDON (Physiological Laboratory)—5 P.M. Dr A. D Waller: On the Action of Anæsthetics and Narcotics. (Lecture on Advanced Physiology)

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* 'TO THE EDITORS,' and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed 'To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol. II. of 1902, which was completed with the issue of Dec 27th, and the Title-page to the Volume, were given in THE LANCET of Jan. 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half-year's numbers are also ready Cloth, gilt lettered, price 2*s*. by post 2*s* 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423, Strand, W C are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c. should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Lettsomian Lectures

ON

THE CONDITIONS WHICH MODIFY THE CHARACTERS OF INFLAMMATIONS OF THE SKIN, AND THEIR INFLUENCE ON TREATMENT

Delivered before the Medical Society of London

BY H RADCLIFFE CROCKER, M D, F R C P LOND,
PHYSICIAN TO THE SKIN DEPARTMENT UNIVERSITY COLLEGE HOSPITAL.

LECTURE I[1]

Delivered on Feb 16th 1903

MR. PRESIDENT AND FELLOWS,—Let me first thank you for the honour you have done me in electing me your Lettsomian Lecturer, though when I looked down the list of my distinguished predecessors I can only say that my temerity in accepting the responsibility has weighed upon me ever since I assented to do so, and all the more so, because the time afforded for the preparation of the lectures has been much curtailed by the unexpected prolongation of a previous task.

It is just about a century ago that Dr Robert Willan was issuing in parts his work on inflammations of the skin which was published in its complete form in 1808 He was a distinguished member of this society and was the second recipient of the Fothergillian gold medal in 1790 for the outline of his plan for the arrangement and description of cutaneous diseases. Although there had been previous attempts by Lorry, Plenck, and Alibert to present the study of skin diseases in an intelligible form it is not too much to say that Willan's treatise was so far in advance of its predecessors that he may be regarded as the father of modern dermatology and that his work, from its practical character, gave the study of skin diseases an impetus which it has never lost, and it will not, I trust, therefore, be a waste of time to glance briefly at his views before I show you how the subject may be regarded at the present day Willan looked at the matter entirely from its clinical aspect and divided inflammations of the skin into papular, scaly, vesicular bullous and pustular forms, the divisions depending on the most prominent clinical feature of the disease, although he was well aware that some diseases might pass from one phase to another—as papular into scaly and vesicular into pustular For many forms of inflammation his knowledge was not sufficient to connect different phases of the same disease together and so they were given a different name which our improved knowledge has shown to be unnecessary Willan was, in fact, the Linnæus of dermatology, and although his classification was artificial it was a very practical one, and even now we consciously or unconsciously often adopt the same division in our minds in the diagnosis of any particular case. For instance, if we have before us a vesicular eruption if we do not at once recognise it we go over all the vesicular diseases we know of and endeavour to fit the particular case into some known category I do not intend to prolong the accounts of Willan's early efforts, but it was the first real attempt to analyse carefully and to arrange the skin diseases he met with according to their clinical features, and so far as actual clinical description is concerned it was so accurate that it holds good now and ever will do so The analytical method also has been continued even to the present time, and to a more limited extent is still going on. Thus during the last ten years more than a dozen distinct clinical forms of disease have been differentiated and necessarily labeled and though they are for the most part very rare affections there can be no question that they are really separate forms of disease and that some, like acanthosis nigricans, which is often associated with visceral cancer, or the so-called bronze diabetes or the morbus cœruleus and chloroma, are intimately connected with general medicine.

It is not, however, these new forms of disease to which I desire to draw your attention in these lectures, but to present the other side of the picture—to show the progress which has been made in the last century and is still going on in what I may call the synthesis of disease and how our increased clinical and pathological knowledge is grouping diseases together which we had not known to be connected, and how certain processes, either separate or combined, modify the clinical features and are modified by other conditions of the individual attacked, and I shall endeavour to show that the knowledge of those processes and conditions exercises a decided influence in the successful treatment of many eruptions

In selecting the subject of inflammations of the skin I have also been influenced by the fact that they include more than half of all skin diseases, six out of every ten patients with skin eruptions having some form of inflammation, therefore every medical man must have many cases come before him for diagnosis and treatment. In 10,000 of my hospital cases nearly 6000 were inflammations and over two-thirds of these were included under three diseases—eczema, psoriasis, and impetigo contagiosa—while five-sixths were comprised in these diseases and three others, lichen planus, erythema, and urticaria. In my private practice the total was nearly the same, but the components were in different proportions As might be anticipated, the number of cases of contagious impetigo was small Eczema and psoriasis still headed the list in not quite so large a proportion. Lichen planus was more than twice as frequent, while the disfiguring acnes were nearly three times the number of the hospital cases, and the erythemata and urticarias were in nearly the same proportion

Let us first consider inflammation of the skin set up by irritants either in the course of the occupation of the individual or applied intentionally, or unintentionally, in various circumstances. Irritants, judged by the kind of dermatitis which they set up, may be divided into two classes—those which are so strong that they set up a violent inflammation in any skin exposed to their action and those of a milder character which only excite inflammation in a comparatively small number of those exposed to them, and in whom, therefore, there must be a special vulnerability, either natural or acquired. The first class are usually distinctive in so far that a practised eye can tell at once that it is an irritant dermatitis that has been present, and in many cases the actual irritant is demonstrated. Take, for instance, this drawing[2] It is at once obvious that these vesicles all over the palm are due to an irritant The yellow colour is due to aurantia, a yellow dye whose chemical name is hexa-nitro-phenyl amine. It is much used for cheap yellow shoes and other leather goods Apart from the colour, the abundant uniform sized vesicles, thickly crowded but without any arrangement, stamp this as an artificial eruption quite different from any form of what may be called natural dermatitis Contrast it, for example with the similar lesions of a chronic vesicular and pustular sweat eruption of the palm or of acute pompholyx, where the large and variable size of the lesions is so different. Here, again, is a bullous and erythematous inflammation excited artificially by a girl, aged 12 years, with a strong caustic applied with a broad brush, presumably from a morbid desire to excite sympathy The direction of the lesions the brush marks being distinctly visible, sloping from without inwards, enables its character to be easily recognised. Then I show three burns which are quite distinctive in their characters, produced by Roentgen rays, which have this awkward peculiarity, that they produce no visible or sensory effect at the time and the inflammation may not set in for days or even two or three weeks, after the last exposure This is a great drawback to their therapeutic employment in which it is often necessary to go on until there is a slight visible redness which may become a sudden severe dermatitis a week or two later In these three cases, the exposures were for radiographic diagnosis of the kidney and prolonged beyond what is necessary nowadays with improved apparatus All the lesions were in the centre of the abdomen. Case 1 was due to an hour's exposure, and although there was some redness the next day the severer inflammation set in six days later It took two months to heal. In the second case there were several long exposures, and the dry black slough remained for months without alteration or separation In the third case, healing has not been more complete than the drawing shows in six years, and this network of dilated vessels marks the original area of inflammation. The slowness of healing and this telangiectasic condition are characteristic of Roentgen ray burns and I have even seen telangiectasis produced without any antecedent inflammation. As regards the effects of milder irritatants the diagnosis in the absence of a history of exposure to such irritant may be, and often is, impossible, but if there have been repeated apparently causeless attacks, their primary effect being always on an exposed part may afford some clue. Perhaps one of the most frequent puzzles of this kind arises when amateur horticulturists get a severe dermatitis from exposure to some irritant plant of which the pretty primula obconica is the most frequent offender I have met with several cases in which pemphigus or acute eczema has been diagnosed and internal treatment and a rigid dietary have been enjoined, of course without effect

---

[1] Lectures II and III. will be delivered on March 2nd and 16th, 1903 respectively

[2] In the lecture drawings and plates were shown in illustration

The vulnerability of the patient, whether natural or acquired, very often increases after each attack until a sensitiveness almost incredible may be acquired Iodoform dermatitis, to which some surgeons as well as their patients are liable, is a familiar example and Dr A J Hall of Sheffield relates a case of an analytical chemist who acquired an idiosyncrasy with regard to phenyl hydrazin hypochloride to such an extent that the primary local inflammation not only became general in a few hours but the minute quantity of vapour conveyed in the clothes of an assistant who visited him at his own house to report on his work on this substance was enough to excite an outbreak.

There is quite a large class of trade eczemas, either from dry or wet substances, such as those seen in bricklayers, bakers, grocers, barmaids, or French polishers, of which baker's eczema is sufficient as an example, and the point I wish to emphasise is that not only is there inflammation of the part exposed but in many of these patients a symmetrical eruption in distant parts may develop in a few days, or even hours, absolutely indistinguishable from the so-called idiopathic eczema. The outbreak is often too sudden, too widespread, and too symmetrical for the inflammation to have extended from without, and we must assume either that it is a reflex nerve disturbance of a vaso motor character or that it is due to micro organisms multiplying first at the site of the dermatitis, then absorbed into the circulation, or that some toxin is developed and so absorbed and distributed At all events, the result is that this inflammation of external origin cannot be logically separated by its external aspect from one primarily generated from within, and very often in the course it subsequently runs, though local inflammations which do not afterwards become general are, as a rule, readily amenable to treatment Restricting for the moment eczema to its papulo-vesicular type we have a strange confession to make—that though eczema in its varying manifestations is the commonest of all skin diseases, constituting about one third of all forms of eruption, and has been closely studied by physicians, both general and special, for the last 100 years, yet we are still as far from agreement as to its pathology as ever In the discussions on eczema at the Paris Congress of 1900 the consensus of opinion undoubtedly was that in the papulo-vesicular inflammations of the skin which are universally included under eczema no specific organism could be considered as its cause and certainly not the morococcus of Unna which was generally considered to be a modification of the common staphylococcus pyogenes albus, which is universally present in the skin and under ordinary conditions is a harmless organism. Moreover, some of the best bacteriologists showed that eczema vesicles could and did exist in which the fluid contents were absolutely free from organisms, though, on the other hand, Galloway showed that the universal staphylococcus pyogenes albus might exist in uncomplicated and early lesions of papulo vesicular eczema, as, indeed, it exists in the normal skin also We must therefore conclude that these organisms are not of themselves sufficient to produce a papulo vesicular dermatitis, but it is highly probable that given certain conditions, such as gouty or other cause of faulty assimilation, the action of an irritant on the skin in a predisposed person, a nerve shock, either purely mental, such as a great grief, worry, or anxiety, or a physical shock, such as a fall or strain, that these usually harmless organisms may become pathogenic and give rise to one of those forms of dermatitis to which we universally accord the name of eczema.

To the questions, therefore, Is eczema parasitic? Is it a blood dyscrasia? Or is it a neurosis? not only cannot an absolute answer be given as regards any one of these factors, but I believe it is not only the most cautious attitude but the one which will lead to the soundest and most successful practice if instead of tying our hands by adhering to any one theory we allow that all these factors may, and often do, have some share and that our endeavour should be to estimate what proportion these several factors may play in any particular case If we try to do this intelligently we shall have to recognise that our patient is not a mere test tube in which we have only to neutralise the uric acid in order to cure his eczema, or that if we kill the hypothetical germ that the inflammation will forthwith cease, and still less shall we rely upon arsenic as the panacea for all cutaneous woes and find too often that while the skin irritation is as rampant as ever, we have set up a gastric irritation which may give some trouble to subdue.

While, then, it cannot be shown that any special organism can of itself produce this papulo-vesicular type of dermatitis, yet when once the process is started pus cocci, whether the staphylococcus aureus or the streptococcus pyogenes, can and do modify the form of inflammation presented to us, though it may still be included under the name of eczema. In some cases their presence is probably due to the cultivation into virulence of previously harmless organisms, in others by secondary invasion It is this microbic influence I now propose to consider If we compare a vesicular discharging eczema of the face and arm with a pustular form of the same regions the differences are very striking and all the superadded crusting is entirely due to the pus cocci invasion. Impetiginous eczema, as it was formerly called, was regarded as of a severe and formidable character, and it may be so if neglected, while, on the other hand, if its nature is understood it is readily amenable to treatment planned to destroy the pus cocci, by which the inflammation may be reduced to its simpler uncomplicated character and the whole inflammatory process will sometimes be subdued All that is necessary is to soften and to remove the crusts with carbolised oil, alkaline compresses, or boric acid starch poultices, and then to apply some such ointment as iodoform ten grains and unguentum zinci oxidi one ounce, which is only an example of a whole legion of similar applications There is, on the other hand, a large class of inflammations of the skin and its appendages entirely due to pus cocci, with or without other organisms, of which the following is a list in tabular form according to the most modern views

Staphylococcus aureus, albus citreus	Boils
	Carbuncles
	Coccogenic sycosis
	Lupoid sycosis
	Impetigo of Bockhardt and secondarily in other forms
	Quinquaud's folliculitis decalvans
	Dermatitis papillaris capillitii and probably other forms of pustular folliculitis
	Pemphigus neonatorum
	Pemphigus contagiosus
	Cutaneous abscesses
	Superficial whitlows
	Erysipelas
	Granuloma pyogenicum and other papillary growths
	Acne varioliformis seu necrotica
Streptococcus pyogenes of Fehleisen	Impetigo contagiosa and its varieties, including ecthyma but excepting Bockhardt's
	Erysipelas
	Erysipeloid
	Superficial whitlows

It is not to be inferred that this table covers the whole ground of pustular inflammations, for there are other organisms which can excite pustular lesions without the intervention of pus cocci, such as the trichophyton megalosporon, blastomyces, the tubercle bacillus, &c It will also be observed that erysipelas may be produced by either streptococci or staphylococci, but the streptococcus of Fehleisen is the usual organism. Further, it is contended that some lesions are produced by a mixture of the staphylococcus and streptococcus. Thus it is said that impetigo contagiosa due to the streptococcus pyogenes of Fehleisen may be invaded and modified by the staphylococcus aureus, but this is still a controverted assertion and the point is of academic interest, as the line of treatment would be unaltered even if the statement is true Many of these follicular pustules are the affection which is known as the impetigo of Bockhardt who was among the earliest to identify staphylococcus aureus as its cause. It differs from ordinary impetigo contagiosa in being always pustular from the first and in being a folliculitis connected with the hairs, most commonly of the scalp, where it may come on either as a crop of follicular pustules or it may attack primarily or secondarily the neck, face, back, buttocks, or thighs. I have gone out of my way to describe this condition because, according to Sabouraud, it is always the precursor of boils, sometimes leads to abscesses, and secondarily invades the streptococcal form of impetigo contagiosa. Although I think Sabouraud is too sweeping in his assertions that this form of impetigo always precedes boils it is certainly a frequent concomitant and it is of great importance that it should be cured as soon as possible. As a warning not to let pustular affections alone I have seen a streptococcal impetigo following vaccination which was allowed to go on with inadequate treatment lead to a rapidly spreading erysipelas over a great part of the body, which endangered the child's life and gave as much anxiety to the medical attendant as it did to the parent.

In all these diseases the realisation of the fact that pus organisms are the *fons et origo mali* is essential to successful treatment. The local destruction as soon as possible of these organisms is the key to stopping boils and carbuncles not only at the moment by preventing their further development, but still more in stopping the supply of future boils. Thus subcutaneous injection of a 1 in 30 solution of carbolic acid round a carbuncle will stop its extension, while in the case of boils, if each boil is at once opened and disinfected with 1 in 40 carbolic solution, not only do the lesions heal more rapidly but in a short time fresh boils cease to appear. Consider for a moment what an immense practical gain this is. There is a definite aim in the treatment, a known organism which can be fought successfully even when the liability to boils has been going on for months or years. But to do this the lesions must be attacked at the earliest possible stage, as the pus cocci may have spread beyond the site of a fully-developed boil before it is opened. Every pustule, however small or however superficial, should be at once opened, thoroughly disinfected, and in the case of these small lesions the patient can often be instructed what to do for himself, as time is important and 24 hours' delay may cause the failure of prophylactic treatment as far as that particular boil is concerned.

I propose only to draw attention to two other of these primary pus cocci affections before I pass on to another form of dermatitis. One of these is pemphigus neonatorum. This, as its name implies, is an affection which attacks newly born infants in the first week or two of life. It occurs in the form of blebs from one-eighth to half an inch in diameter, usually with pellucid contents, and very frequently begins about the genitals and spreads slowly or rapidly over a large area. It is sometimes mistaken for a syphilide, but it is not pustular from the first, does not especially attack the hands and feet, and the child is not as a rule cachectic; moreover if properly treated it is benign and short in its course. For several years past Pernet, Nabarro and others from cases in my clinique have obtained pure cultures of staphylococcus aureus both in solid and liquid media, but the streptococcus has also been found by some observers. These cases are specially frequent among the poor, where defective drains and similar unhygienic conditions prevail, and the disease was often endemic in lying-in institutions before modern antisepticism was practised. All that is usually required is to remove the child from bad surroundings and dust on freely a powder of boric acid 10 per cent. with zinc and starch. But in neglected cases or where the affection is derived from the mother who is suffering from puerperal fever a general and fatal septicæmia may result.

Another class of pus organism diseases which are not yet generally so recognised are the fungating papillary growths which are apt to form in all chronic suppurative surfaces and after some acute suppurations. They are all varieties of pyogenic granuloma, but have received different names according to the underlying conditions on which they develop. Thus there may be a papillary growth on a chronic ulcerating syphilide or a similar development on a scrofulous sore, usually called lupus papillomatosus. Another form occurs in the folds of the axillæ and groins in pemphigus vegetans. The fungation, sometimes seen in coccogenic sycosis, is entirely due, in my opinion, to pus cocci. Of late years a supposed new disease has been described and called botryomycosis hominis; veterinary surgeons first gave the name to a fungating granuloma seen after castrating various animals and it was wrongly thought to be a botryomycosis. As it occurs in man, it is usually seen after suppuration on the palmar surface of the hand and is now pretty generally acknowledged to be due to pus cocci infection and only a pedicled tumour-like exaggeration of what used to be called proud flesh. Ligature and iodoform speedily cures it, and all the conditions I have mentioned, to which may be added the granuloma inguinale tropicum and its home imitators, may also be cured on similar principles. Finally, I would add that, in my opinion, although I cannot give definite proof, hypertrophic scars such as follow burns, vaccination sometimes and other slow healing sores, are also the result of pus cocci invasion, and that if these organisms were excluded during the healing process no such scar thickening would result.

Thus we find the same organisms producing such divers lesions as bullæ, superficial and deep pustules, boils, carbuncles, fungating granulations and keloidal thickening of scars, and various forms of folliculitis—a very important generalisation therefore which should exercise a strong influence on our practice. Note, too, how far it takes us from Willan's morphological classification founded on primary lesions. The shape the lesions take depends on the anatomical position of these pus organisms in the skin, not on the nature of the organism itself; and even pus which is present in nearly all lesions is absent in pemphigus neonatorum. The recognition of their common origin therefore is entirely due to modern pathological research and holds out promise of still more fruit to be garnered by similar investigations in other directions.

I have shown how a local irritant on a predisposed person may excite an eczema and how the invasion of pus cocci on the dermatitis may modify it, and if they are conveyed and inoculated on to other parts of the skin the numerous and even dangerous conditions they may arouse. I wish now to direct attention to the modifications a dermatitis may undergo if it is excited on what may be called a seborrhœic basis. These are generally admitted to be of bacillary origin, but the term seborrhœa requires a little explanation as there has been a good deal of controversy about it of late years. As all know, its primary meaning is an increase of the secretion of sebaceous glands and according to the strictest interpretation only cases with an excess of oiliness of the scalp or skin come under this term, and even of this Unna and his school say that the oiliness comes from the sweat glands rather than from the sebaceous glands. This view has been strongly combated and is losing ground. Sabouraud states that seborrhœa oleosa is due to the presence of his special seborrhœic micro-bacillus in the sebaceous glands and that it is also the cause of the comedo which is a cystic formation round these micro-bacilli producing the familiar primitive fatty plug. But in addition to this excess of oiliness, which may be seen both on the face and scalp and is a source of great annoyance to the patient, a still more common condition is to see the scalp covered, more or less with a firm fatty incrustation, varying from soft yellow wax to a scaliness of a more or less greasy character. This has also hitherto been included under the term seborrhœa and it is convenient clinically, though not quite correct to do so still. When it is scraped off the skin beneath is perfectly white, and it may go on for years without clinical signs of inflammation; nevertheless microscopically there is a dry catarrh of the skin and the firm secretion is really a mixture of fat with epithelial cells derived chiefly if not entirely, from the horny layers of the epidermis. It is therefore a fatty pityriasis of the scalp due it is said, to Malassez's bottle bacillus. Unna's 'morococcus' is in his opinion, the cause of both seborrhœa in its most extended sense and also of the various obviously inflammatory affections which spring from it, while Sabouraud, more correctly, I think, regards the seborrhœic micro-bacillus as the primary cause of the true seborrhœa oleosa, and considers the fatty pityriasis to be due to the combination of the bottle and seborrhœic micro-bacillus, while the secondary invasion of staphylococcus aureus or a grey coloured coccus produces various inflammations which may be included under the convenient term 'seborrhœides.' We need not decide whether this view is rigidly correct, the important point to remember is that the 'seborrhœas' both oily and firm, are affections due to one or more micro-organisms and are not the trivial conditions they appear to be to most persons. For unless there is an active dermatitis either on the scalp or glabrous skin the patient rarely comes complaining of an oily or scurfy head, but only of the hair coming out, so that he is threatened with baldness, and in nine cases out of ten this defluvium capillorum is the result of seborrhœa. It is not my intention to go minutely into this subject, which would require a lecture to itself, but to point out the principles of treatment which a more intelligent knowledge of the subject has suggested and of which experience has confirmed the value. In former days, not very long removed from the best of us and still existing in many medical minds, the one idea was that falling of the hair was due to debility and feeble nutrition and the universal practice was to give tonics and apply cantharides and other stimulants locally to improve the circulation. Of course there are cases after fevers and other serious illnesses which require, or, at all events, do well with, such treatment, but they form a very small proportion of the cases, and the recognition of the microbic origin of the disease, while it should not make us neglect the investigation of the general health, should lead to the use of microbicide applications for if the microbes are destroyed the chief obstruction to the growth of the hair is removed and the hair grows readily enough unless the follicles and papillæ are too much damaged to recover. Preliminary to this is the removal of the oily or fatty layer by means of soft-soap applications which may be combined with antiseptics such as thymol or carbolic acid. Afterwards the application of such microbicides as resorcin, sulphur, mercurials, iodine, &c. are usually successful. These are only examples of the kind of application experience has taught to be most efficacious in destroying the seborrhœic micro-bacillus, and these or similar drugs were used long before Sabouraud's observations gave a more lucid explanation of the process than had previously been afforded by Malassez's, Elliot's, or even Unna's observations.

In addition to stopping the fall of the hair and paving the way to its restoration the cure of seborrhœa takes away what I have been insisting on as a strongly predisposing factor in the production of active inflammation of the skin, either by its own microbe taking on increased pathogenic activity or by its offering a favourable nidus for the cultivation of other germs, especially staphylococci and streptococci. This is all the more important if the patient has had previous attacks of dermatitis either of this type or other types, as one of the places of least resistance is thus removed.

Let me give an instance, as illustrated in this plate.[3] This woman, aged 50 years, had had seborrhœic pityriasis capitis for years, with no other symptoms beyond occasional slight itching and a gradual defluvium capillorum which had left very little hair. One day she learnt that her husband, whom she imagined to be in prosperous circumstances, was a bankrupt and as one consequence a very active inflammation of the scalp supervened which is depicted here on the scalp, but her hands were also inflamed very much as in the plate, though, as a matter of fact, the drawing was not taken from her hand; further, the matrix of the nails became involved and the nails themselves became discoloured, deformed, and hypertrophied, leading to the enormous overgrowth shown in the drawing and in every way her condition for a long time was a very unhappy one.

The seborrhœides are of two classes: (1) those which are the direct outcome of seborrhœa; and (2) those which are indirectly due to it. The direct ones imitate forms of non-seborrhœic dermatitis, but with distinct differences. One imitates eczema, but usually in a dry form, in patches which have well defined borders, have frequently a rounded outline, sometimes definitely circular, and have especial seats of election, such as the neck, the centre of the chest and back, and the axillæ and groins, though no place can be said to be exempt. When very extensive—and it may affect nearly the whole body—it presents appearances closely resembling the pre-mycotic stage of mycosis fungoides, a formidable and fatal disease in which in the latter stages fungating tumours develop. In the early stage of this form there are always gaps of healthy skin, surrounded by a dry, finely scaly dermatitis with raised, well-defined borders, so that the normal skin has the appearance of being sunk below the general surface, though, of course, it is due to the morbid tissue being raised. The resemblance is so close that many cases of mycosis fungoides in the early stage have been diagnosed by good observers as seborrhœides, but the converse is not likely to happen, as mycosis fungoides is rare and unlikely to be thought of when an innocent looking inflammation of a not very rare kind is apparently presented, and its absolute intractability to treatment may be the first circumstance to raise doubts as to the correctness of the diagnosis. The second or papular form is generally easily recognised by its localisation to the centre and upper part of the trunk, back and front, though occasionally it goes beyond these limits. It forms small circles of closely aggregated papules with a fawn coloured centre and by coalescence of the component circles a very characteristic, gyrately outlined patch with brownish yellow centre may be produced in the interscapular region. This form is interesting because it was the first inflammatory disease which was recognised by Duhring to be constantly associated with seborrhœa capitis and called by him seborrhœa corporis long before Unna's important generalisation gave a more extended application to seborrhœic dermatitis. Though easily recognised it is often difficult to cure because while removeable for a time it has a strong tendency to recur, especially if the seborrhœa capitis is not efficiently treated, so that recrudescences should be looked out for and promptly dealt with. The third or psoriasiform seborrhœide is a fairly close imitation of psoriasis but differs in its seat of election by attacking chiefly the axillæ and trunk instead of the limbs. The patches are as a rule less definitely circular, less scaly, the scales being more often fatty and opaque instead of dry and silvery, and while both diseases attack the scalp, true psoriasis has very little effect on the hair growth, while the seborrhœide produces considerable loss of hair, associated as it always is with a general seborrhœa capitis. These patches are very little influenced by arsenic and generally yield best to a mercurial application such as the yellow oxide or ammoniated mercury ointment or to resorcin and sulphur from 10 to 20 grains to the ounce. According to Unna, psoriasis itself is a final link in the seborrhœic chain, but most dermatologists do not follow him so far as that and think that he has been led by parental fondness for the family he has done so much to create to bring too many strangers into kinship with it.

The indirectly related affections to seborrhœa are, according to Sabouraud, mixed infections—the pustular eruptions, acne varioliformis, acneic furunculosis, chronic furunculosis of the neck, sycosis, acne keloid, and *dermatitis papillaris capillitii*. These are all, he says, due to the secondary invasion of the staphylococcus aureus on the seborrhœic basis. Although this is not absolutely proved it may be accepted provisionally and if correct it is a nearly as important generalisation as Unna's with regard to the direct scaly seborrhœides and just as we find the pus cocci on an ordinary eczematous dermatitis profoundly modify the form of inflammation, so here the same organisms on a seborrhœic basis exercise a no less important modification of character and give rise to absolutely new forms of disease. It therefore opens to us new doors for investigation as to the clinical changes produced in other directions either as regards the primary conditions or the secondary invasion. Even if this compound origin is not absolutely true it is indisputable that pus organisms play an important rôle in these diseases and our aim in treatment must be to get rid of them.

THE LOCAL ORIGIN OF SOME GENERAL AND SYMMETRICAL ERUPTIONS.

It is obvious that when we have to do with a general and symmetrical eruption that this symmetry combined with a wide extent is a sign of its distribution having occurred from within outwards, while in diseases admittedly due to external parasites, such as impetigo contagiosa from pus cocci or ringworm from the trichophyton, their asymmetry, and what we may call their haphazard distribution, are important features in their diagnosis. In certain diseases, however, it can be shown, sometimes with strong probability, sometimes with certainty, that while in the latter stage or in their recurrences they are widespread and symmetrical, in the primary invasion this is not the case and that they may commence on one side and remain so for a considerable time and then generalise symmetrically more or less rapidly from that. This mode of development is from a primary patch.

The primary patch.—There is a disease called pityriasis rosea to which I would call attention for a few moments. It is noteworthy because it is not very rare, but it is a disease little known to those who do not study dermatology. It may cover the whole trunk and greater part of the limbs and in cases which develop rapidly it may be accompanied with enlarged post-sterno-mastoid glands, slight congestion of the fauces, and a slight rise of temperature, while the eruption is in many cases like the early papulo-scaly syphilide. It usually runs a course of from three to six weeks and then disappears spontaneously, but occasionally it lasts from three to four months. Its mode of development is very important, Brocq, a French dermatologist, first pointed out that it began as a single circular patch on some part of the trunk which slowly increased in size up to a shilling or rather larger, and in about ten days from its first appearance began to generalise and would often cover a large area, or even the whole body, in a few days The explanation I would offer is that there is at first a local multiplication of microbes and then absorption takes place and rapid multiplication in the blood I have traced the same mode of development in more chronic diseases especially in their first attack, but not in recurrences. Thus in the first attack of psoriasis it will be observed that there are often only one or two patches on one limb, these will enlarge peripherally, generally very slowly, and may remain for weeks or months, and in some cases for years, with very little change and then gradually or rapidly the patches increase in number When the increase is gradual the patches multiply asymmetrically and often on the same side as the original patch and on any part of the limb but when it is rapid the multiplication is bilateral and symmetrical and in the usual seats of selection—elbows knees and extensor aspects generally This suggests that in the gradual multiplication fresh patches are formed by implantation of micro-organisms from without, while in the generalised cases multiplication comes from within, the microbes or their toxins from the original patches being absorbed into the circulation. In the recurrences symmetrical and often widespread attacks occur at once and no primary patch is observed, but patients suffering from psoriasis very often have remanets from former attacks which do not trouble them and which they therefore allow to remain untreated and from these a fresh outbreak often starts. In lichen planus a similar phenomenon can often be traced. In many cases a few chronic patches have been present for months or years and then generalisation takes place

---

[3] Author's Atlas, Plate lxxx.

With regard to eczema the evidence is not quite so definite, but, as I have already pointed out, there are many instances in which a dermatitis originated by a local irritant became general in the form of a typical acute eczema. It is obvious from this that it is very important to treat the beginning of skin diseases, and it is highly probable that in those diseases which have a primary patch that not only would a generalised outbreak be prevented but in a recurrent disease like psoriasis the complete removal of the early patches before the general system was infected might be the means of a real cure, so that recurrence would be prevented. Further, it shows the importance of impressing upon the patient that every fragment of disease should be removed, even in the recurrences, as it affords the best chance of preventing future attacks

If I have been able to carry you along with me in the discussion of these various forms of dermatitis you will now perceive that in spite of their varied morphology there are large groups with a central pathological core, so to speak, in each group which show that the same micro-organism may produce most diverse effects according to its mode and depth of implantation and still more according to the soil in which it is planted, and whether it is on healthy or what may be called virgin soil, or whether it is superimposed on ground which has been ploughed and harrowed by antecedent morbid conditions whether produced or not by previous micro-organisms of a different character While each different form of disease necessarily has a separate name, so that it may be docketed and arranged from a clinical point of view, the new conception of the relationship of these diseases founded on their pathology gives us a breadth of view that goes far beyond mere nomenclature and will help to acquit dermatology in its modern aspects of being a mere farrago of outlandish names. It is partly for this reason that, while pointing out illustrations of many forms of diseases more or less closely allied, I have used as few names as possible, as I wish to emphasise the importance of processes rather than names, and that the same process might in different circumstances produce very different clinical results, which seen from a correct pathological standpoint were recognisable as closely related members of the same family which required the same principles of treatment, though possibly with modifications in each case to secure the full amount of efficiency

In the directly seborrhœic inflammations such as the papular eczemiform or psoriasiform eruptions, sulphur, resorcin, ichthyol, and thymol play an important part, but in small quantities such as 1 per cent. in the oleates or zinc or lead ointments or a mild form of mercury such as the ammoniated or yellow oxide, 2 to 4 per cent, either singly or combined, may be rubbed in more or less vigorously according to the degree of the inflammation. When the inflammation is more intense the treatment at first is the same as for acute vesicular eczema, but one of the drugs previously mentioned can be advantageously added at a comparatively early stage If the inflammation is one of those in which there is a good reason to believe that pus cocci are superadded to the seborrhœic micro-bacillus then means for their destruction must be adopted, but while the principles and the drugs may be the same as in pus cocci invasion or ordinary eczema we find in practice that it is more difficult to produce their complete extirpation and that the closest following up of the treatment is required to prevent recrudescences of a disease which we have often scotched but not killed. Since they are often intra follicular probably the pus cocci invasion goes deeper when the way has been prepared by the seborrhœic micro bacillus and it is therefore more difficult to produce their complete destruction, though frequently the removal of all the more superficially situated organisms will produce quiescence for weeks or months or even longer This quiescence of germs when they are shut off from the air occurs in many diseases, and while it serves to account for many apparently causeless recurrences it is not always intelligible why this dormancy should sometimes last so long, as the epidermic cells are supposed to be always tending to work to the surface.

Although I have hitherto spoken only of certain external conditions affecting the skin and their treatment I do not wish it to be supposed that because modern research has revealed various micro-organisms and partially unravelled their mode of origin invasion, and effects, we have simply to treat all these conditions by the external application of microbicides and the skin will be restored *ad integrum*—in short, that the microbe is everything and the man nothing While I have hitherto confined my attention to this aspect or the case, I hope in my next lecture to discuss some of the conditions of the patient which influence disease and show how they may be combated.

ON

FIBROIDS OF THE UTERUS AND ITS LIGAMENTS CONSIDERED FROM A CLINICAL AND SURGICAL STANDPOINT

Delivered before the Harveian Society of London on Nov 6th, 13th and 20th, 1902,

BY ALBAN H G DORAN, F R C S ENG,
SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN MARYLEBONE ROAD N W

LECTURE III.[1]

Delivered on Nov 20th, 1902

THE MANAGEMENT OF CAPSULES

MR. PRESIDENT AND GENTLEMEN,—When a burrowing fibroid is shelled out of its capsule of broad ligament the tissues usually shrink so that little or no trimming is needed. Vessels have always to be secured on the inner or parametric surface of the capsule. Some operators allow the capsule to remain open and to drop down into Douglas's pouch after ligature of its vessels, the oozing being absorbed by the peritoneum. Mr Knowsley Thornton[2] observes "I have never been able to understand the great trouble taken by most abdominal surgeons to shut off stumps and raw surfaces from the peritoneum. All experience shows that if the operation be aseptic effusions of blood are much more rapidly and harmlessly absorbed by the peritoneum than by torn and cut cellular tissue and experience likewise teaches that adhesions to any raw surface left free on the peritoneum are very rare Damaged surfaces, on which peritoneum remains, much more frequently adhere. If asepticity be not quite assured, it is easy to drain with a glass tube. In my opinion, it is infinitely more dangerous to shut up cut and torn tissues."

[2] Allbutt and Playfair's System of Gynæcology article Hysterectomy" p. 627

Thus spoke a surgeon of high authority on abdominal surgery, a witness of the good as well as of the evil in methods of operating and treatment now considered effete A younger British operator teaches opposite principles and practice. Dr William Duncan[3] wrote two years ago "In the cases in which the tumour grows between the layers of the broad ligament, after it has been shelled out a raw cavity is left. This cavity is best treated by whipping the walls securely together from below upwards (after hæmorrhage has been stopped) by means of a continuous silk suture, and thus the necessity for drainage by a tube or by iodoform gauze is obviated" Dr Howard Kelly[4] differs a little from Dr Duncan. He directs that the peritoneal flaps should be sewn together over the stump after the turning in of the pedicles of the ovarian vessels, but adds that "if there is a large space left in the cellular tissue it will be best to unite the peritoneum with interrupted or mattress sutures, so that any blood which escapes from capillaries will run into the peritoneum and be absorbed instead of forming a hæmatocele"

I am not surprised to find that three operators of experience differ in their management of capsules, and I believe that the last word has not been said on the matter, or rather I do not see that any rule can apply to every case When there is not likely to be any effusion, as in cases where the enucleation is not extensive and the capsule, consisting of little more than the two flaps of the opened up broad ligament, shrinks to very small proportions, the turning in of everything that can be pushed under the flaps is in the highest degree advisable Whenever I have adopted the practice, under the conditions just stated be it understood, I have noted that all went well, pulse, temperature, excretion of urine, passage of flatus, and general condition included But this neat and surgical tucking in practice is unsuited to cases where the capsule is deep, forming a big cavity below the two flaps of peritoneum. We know from experience that it is not very difficult to avoid mischief on the peritoneal side of the flaps whilst it is not easy to insure the patient against complications caused by prejudicial changes in the parametrium under the flaps, complications specially probable when the enucleation has been extensive The principles of the three writers already quoted are less at variance than they appear to be at first sight Mr Thornton is right in teaching that the peritoneum is a better absorber of blood than the parametrium It follows that Dr Howard Kelly is also right in applying sutures to the flap in such a manner that the oozing blood may run out of the parametrium into the peritoneal cavity As the surgeon in the process of enucleation makes a parametric cavity, an unnatural space, Dr Duncan is right in his principles of closing it His precise line of practice may, on the other hand, lead to complications

Let us deliberately consider this question of the flaps We may put aside all thoughts about the stump of the cervix and assume that it has been either cut away or else so treated as to secure it from hæmorrhage without risk of sloughing from unskilful application of ligatures We have to consider at present the treatment of a big cavity left in the parametrium after enucleation The peritoneum tolerates a great deal of handling and ligatures, though when it is damaged beyond its powers of endurance the patient is placed in great and immediate peril The parametrium is less tolerant. It is inevitably bruised during an enucleation, and it does not bear bruising well It tolerates foreign bodies very badly, now after hysterectomy it often has to hold clot, which is pathologically a foreign body, and it must of necessity contain ligatures which more literally come under that denomination. Hence certain complications are apt to follow hysterectomy and panhysterectomy where there has been extensive enucleation, complications seldom deadly like septic peritonitis but often chronic and intractable, tormenting to the patient, and discreditable to the surgeon and to the operation itself These late complications do not always appear in statistical tables Owing to the reparative powers of the serous membrane the peritoneal flaps seldom fail to unite. Their edges begin to adhere in a few hours like the margins of the serous layer of an abdominal wound The dangers of septic infection of the peritoneum are soon averted, usually never to return as far as the capsule is concerned, sloughing of the stump may cause it, but that complication is not under consideration. Later trouble arises from the extra peritoneal or subperitoneal relations of the capsule The patient often does well for a week, a month, or longer after the healing of the peritoneal wound. Then comes trouble which is usually manifested not so much by local pain as by rise of temperature The pulse, though quick, is usually not weak and the constitutional symptoms are not so marked as the condition of the pelvic organs found on examination might lead an inexperienced observer to expect In short, all the familiar symptoms of parametritis or pelvic cellulitis are present. The cause of the parametritis is suppuration of a hæmatocele or a phlegmon developed around an infected ligature. I have said nothing about the early bursting of a hæmatocele into the peritoneum, as that accident is rare and comes surgically under the same category as slipping of a ligature. The hæmatocele formed by the pent-up blood oozing into the parametrium tends to undergo the usual pathological changes even when big enough to rise above the pelvic brim Soft at first, it becomes hard Then it may be, and generally is, absorbed Unfortunately infection is always possible during this retrogressive change, then comes fresh softening, that is to say, abscess heralded by the earlier signs of parametritis. Suppuration is also the result of infection of a ligature This accident leads at once to parametric deposit. Hard at first, it becomes soft, but the softening sets in much earlier than in a mild case of parametritis after labour so that fluctuation can soon be detected

Thus suppuration occurs from two causes, themselves the effect of infection The germ must in many cases come from the intestine When a large tumour is enucleated from the posterior layer of the mesometrium its base is often in close contact with the rectum, as I explained when I demonstrated the surgical anatomy of the broad ligament Thus after enucleation and closure of the flaps clot and ligatures lie in damaged parametric tissue close to the bowel, perhaps on it The abscess will burst. We know the directions in which a parametric abscess may travel before it points. As a rule it bursts into the vagina, not rarely it opens into the rectum Rupture above the groin, common in puerperal parametritis, is unusual in these cases Fortunately the bladder is not often involved in abscess We know that ligatures, ugly things to get into any part of the urinary canal, seem specially prone to make their way into the vesical cavity From what I have observed, however, this objectionable complication is usually, when it follows hysterectomy, the result of inclusion of a piece of the bladder itself in the sutures passed through the anterior flap Hence it is, as a rule, associated with simple cases where there is no enucleation and the flaps are cut thin and too short. When extensive enucleation is necessary the flaps are big and the bladder is not likely to be transfixed by the suture needle. It is ligature silk deep down, far from the bladder and near intestine, that sets up abscess, and it is often discharged with the pus when the abscess bursts into the rectum or vagina. These suppurative changes may develop long after an uninterrupted recovery and then prove very distressing, especially if the patient be upon her travels or away from those who know the nature of the case

I have dwelt designedly on these complications, for I cannot see how the most careful closing of a big gap in the parametrium can guarantee the patient against distant infection Ligatures occasionally set up trouble after the simplest hysterectomy or after an uncomplicated panhysterectomy for fibroid, as in a case done abroad which I examined a few years ago After extensive enucleation such an accident is far more probable. A continuous silk suture applied to the flaps in a simple case may work its way into the vagina, we cannot, therefore, always trust a similar suture fixing together the opposed inner or parametric surfaces of a deep capsule. Besides, in these cases, numerous ligatures have to be applied to the mouths of blood vessels.

Of suppuration and discharging ligatures I have seen many cases which have naturally been registered as "recoveries." In one of my own patients I enucleated and closed a large capsule after carefully securing a number of vessels with

[3] The Modern Treatment of Uterine Fibroids &c THE LANCET April 21st 1900 p 1109

[4] Operative Gynæcology vol ii p 373

No. 1 silk. I checked oozing as much as possible by keeping several sponges pressed down in the capsule whilst other parts of the field of operation were being attended to The pelvic connective tissue was opened up posteriorly as far as the rectum. Parametritis set in early during the third week and an abscess burst into the vagina discharging a ligature and a small piece of sloughing tissue. In a second case I had to enucleate a fibroid outgrowth from the vesico-uterine connective tissue. Two years later two pieces of ligature which I had applied to vessels in the interior of the capsule came away—through bursting of a small abscess into the vagina I know of similar results in the experience of others and I may here repeat that the complication may be met with after panhysterectomy when there has been free enucleation just as it is seen after supracervical hysterectomy I am therefore inclined to think that in cases where the capsule is deep, extending far below the flaps of broad ligament, it may be better surgery to drain it than to close up the flaps. In two recent cases I thought it best to revert to this old practice, excellent when not abused. The results were satisfactory, there was no trace of parametric exudation, and the patient enjoyed perfect comfort after convalescence. There are objections to drainage, no doubt, but the practice is as under rated at the present time as it was once, within our own memory and experience over rated and abused. I am not speaking of peritoneal drainage. Olshausen[5] is not far wrong when he asserts that the routine drainage of Douglas s pouch through the abdominal wound is a "fond delusion." Dr Howard Kelly in his 'Operative Gynæcology' records experiments which show at least that while the tube may possibly help germs out it certainly lets them in With a deep capsule it is otherwise. Its edge can easily be sutured to the lower end of the abdominal wound, so that its cavity is cut off from that of the peritoneum. Then it can be drained so as to be relieved of effusions which it is ill adapted to absorb, whilst there is no danger of infection of the peritoneum. I believe that drainage is beneficial in some cases of deeply burrowing broad ligament and ovarian cysts. A bad case of fæcal fistula came under my care a few years since, it followed about two years after an enucleation by a skilful operator, whilst in a similar case in my own practice where the burrowing cyst had suppurated a sinus developed nearly a year after the operation and gave some trouble.[6] Neither case had been drained. If for any reason drainage of the capsule through the abdominal wound should appear inadvisable, a tube might be passed into the cavity through an incision made from the vagina or gauze introduced the same way But abdominal and vaginal drainage differ surgically and therapeutically in many respects, I cannot here discuss their relative merits.

In conclusion, I beg to remind you that I am no enthusiast about drainage, having seen too much of the results of its abuse. Nor is the drainage of a capacious capsule a practice which can afford the operator much satisfaction. The tissues of the capsule often come away in sloughy fragments and the lower end of the wound is liable to become the seat of hernia. But I know from experience that these evils which (except hernia) mostly appear whilst the patient is still under the operator s care are far less than those which not rarely make themselves manifest many months later in an undrained case, when the operation has been registered as a success and the patient has very likely passed under the care of another medical attendant. Only last June a surgeon practising in New Zealand told me that he attended in January, 1902, a patient who suffered from a sinus in the abdominal walls whence he extracted a loop of stout silk which had been applied over ten years before in the course of an abdominal operation performed by a distinguished operator now deceased I admit that the material of the ligature ought to be considered, but time forbids me to discuss the trustworthiness of sterilised catgut and other substances

ADHESIONS.

Fortunately for the patient and the operator adhesions are remarkably rare in uterine fibroid disease I know no explanation of the fact. The smoothness of the surface of the myoma is not necessarily the reason Smooth it generally is and adhesions are usually absent, but a simple ovarian cyst is smooth, yet adhesions often develop within a few months quite independently of complications such as torsion of the pedicle or peritonitis. Relative mobility has no evident share in causing adhesions, for women often go about for years with freely moveable fibroids, heavy or light, bulky or small, yet when an operation is undertaken not a trace of adhesion may be found. Out of all the series of 44 cases in my after histories already discussed, adhesions were only met with in six, but in one of these, which I will relate, the adhesion, very serious in nature, was due to an exploratory incision and in one the fibroid outgrowth was necrotic and anomalous in form In two fatal cases I encountered very dense adhesions, but in one oöphorectomy had been performed and one had undergone an exploratory operation. Out of the six successful cases, the fibroid was pedunculated and freely moveable in one only, in that instance there was ascites as well, a complication not observed in any of the other five, or, indeed, in any other case in my series of hysterectomies Relative fixity has no distinct relation to adhesions In none of the above cases was there impaction in the pelvis and in several cases where that complication existed old or recent, I found no trace of adhesions In one of the six the tumour was practically fixed owing to partial opening up of the broad ligaments. But in no other uterine fibroid fixed by broad pelvic connexions did I encounter adhesions, nor did I find any in the cases of fibroid of the broad ligament independent of the uterus where I operated. Let me note here that in one of the cases of this form of fibroid the tumour was of enormous size, whilst in another it was a small heavy mass like a cricket-ball lying in the left mesometrium under a large multilocular ovarian cyst

The word "cyst turns our attention to cystic uterine fibroids. As ovarian cysts are often complicated by adhesions, we might expect, going by logic instead of by observation, that adhesions are frequent in cystic uterine fibroids, but this is contrary to my experience A fibroid, by the way, is not truly cystic unless it includes a big cavity containing at least half a pint of fluid. The pathological dilatations of lymphatics which resemble cysts on section are not true cysts and if two or three pints of serum drain away from such a tumour after removal and section the growth is in no sense cystic, but œdematous if not necrotic. I may add here that œdema in itself is no promoter of adhesions Of my own cases of true cystic myoma one held 25 pints of serum and weighed 10 pounds 6 ounces,[7] there was no evidence of sepsis but the patient was overworked and emaciated and had recently suffered from severe abdominal pains. Had the tumour been ovarian adhesions would almost certainly have existed. In another case the contents of the cyst were two pints of turbid red septic fluid and the patient had been laid up for two months with severe abdominal pains. Yet I did not find one single adhesion. The serre-nœud was used in both these cases

The fact that intestinal adhesions are relatively rare is most important for us to remember and most fortunate for the patient who undergoes operation. Small intestine adhesions in a case of a large ovarian cyst are a distinct source of danger A dense adhesion of the ileum is so serious a matter that it is often best to resect the adherent piece of gut. Intestinal adhesions to malignant ovarian tumours are specially perilous But ovariotomy is imperative in a case of ovarian tumour Experience shows on the other hand, that this dangerous complication, intestinal adhesion, is rare in uterine fibroid disease, a much less certainly fatal malady than ovarian tumour, a fact to be considered in the estimation of the risks of hysterectomy for fibroids Most assuredly a very strong factor in the good results of that operation is the rarity of this dangerous form of adhesion. Operators who report their cases should distinguish between true adhesions of the peritoneal surfaces of the intestine and tumour and the adhesion of an extra peritoneal part of the large intestine to the surface of part of a tumour which burrows under and behind the pelvic peritoneum. The rectum is sometimes united to the tumour in this way, then it is not always easy to recognise and its longitudinal bands simulate the ureter or may be taken for strands of fibrous tissue belonging to the tumour • Great care is necessary in enucleating the base of a fibroid which burrows deeply After dividing the pelvic peritoneum too rapid or rough use of the sponge or the finger may result in damage to the rectum, whilst that portion of intestine may be badly torn if the base of the tumour be too smartly pulled up out of the pelvis This accident is not unknown

---

[5] Die Drainage in der Bauchchirurgie eine arge Tauschung ist Veit s Handbuch der Gynäkologie vol. ii. p. 710

[6] Mr Harrison Cripps agrees that such capsules may be drained, but he objects to fixing them to the abdominal wound See Abdominal Section for Ovariotomy St. Bartholomew s Hospital Reports vol. xxix p. 13. My comments on this practice will be found in a communication on the Management of True and False Capsules in Ovariotomy Transactions of the Obstetrical Society vol. xxxix. 1897 p. 255. Suppuration around a ligature has been known to follow the practice of letting the ovarian capsule drop

[7] Large Cystic Myoma of the Uterus of over Twelve Years Duration removed by Enucleation Recovery with notes on Cystic Fibroids Transactions of the Royal Medical and Chirurgical Society vol. lxxvi., 1894

Parietal adhesions the most frequent in ovarian cystic disease, are relatively very rare in cases of uterine fibroid. So much is this the fact that when the operator finds a connexion between the parietes and the tumour he must be very careful and should extend the incision higher till he finds that he can explore the upper limits of the tumour from the peritoneal cavity For what he thinks is a dense parietal peritoneal adhesion is more likely a direct connexion between the abdominal parietes and the tumour, which lies in front of the parietal peritoneum. In this case the fibroid has burrowed under the anterior layer of the mesometrium, as I explained in my first lecture The bladder lies drawn up on the front of the fibroid The consequence of mistaking such a condition for an adhesion to parietal peritoneum is tearing of the bladder, an accident once pretty frequent Fortunately, the use of the serre nœud, otherwise objectionable, had at least one advantage, it taught us to look out for the bladder In so doing we discovered and took into account these displacements of the parietal peritoneum The omentum is the structure most usually adherent When it has long been attached to the fibroid its vessels become enormously enlarged. At the same time its connective tissue often atrophies, so that two or three dilated veins and arteries run almost bare from the non adherent upper part of the omentum on to the surface of the fibroid. I have seen a pulsating vessel one eighth of an inch broad running for quite three inches in this manner, it formed a big loop between two points where it adhered to the surface of the tumour These bare vessels, after all, are mainly curiosities as regards the disappearance of the connective tissue around them. The fact of their dilatation is a more serious matter The omentum should be tied some distance above the adhesion and divided with great care The mouths of the divided vessels should be carefully ligatured with No 1 silk. Thrombosis of omental veins is not unknown, especially when the omentum is fat and thick ligatures are used In one case of ovariotomy where the veins of adherent fat omentum were dilated I suspect this complication occurred, there were severe pain and rise of temperature about the second week and a tender, hard, moveable mass could be felt in the position of the omentum. All the objective and subjective symptoms subsided and the patient recovered

Adhesions of fat omentum associated with a big omental epiplocele are very dangerous The surgeon has to perform radical cure of hernia, formidable in the circumstances, as well as the hysterectomy In a stout woman, aged 49 years, I had great trouble in separating the omentum from the sac and from the fundus of the fibroid as well, the vessels were very big The tumour weighed 15 pounds 3 ounces, it was removed after application of the serre nœud The more modern operation would have been better but the patient did well and is now alive, seven years after the operation.

The worst case of adhesion which I ever encountered was in a case where an exploratory incision had been made just four years before I operated From what I could make out removal of the ovaries was intended but was found impracticable. The flooding continued and the tumour at last grew very rapidly Mr W H. Chamberlain of Northampton sent the patient on to me I found that the cicatrix adhered very firmly to the fibroid Much omentum had first to be separated, it had become firmly incorporated with the parietes, the wall of the uterus, and the cicatricial tissue between them Unfortunately two coils of ileum were involved in the cicatrix. I took every precaution, but both coils were unavoidably torn through all their coats. The rent was longitudinal and about an inch long in both coils. I succeeded in closing the lacerations, using a continuous No 1 silk for the muscular coat and interrupted Lembert sutures of the same material for the peritoneum. Then I removed the tumour and observed before closing the abdominal wound that air passed freely along the repaired coils The operation was rather severe as after the repair of the gut I was obliged to enucleate a big subserous fibroid from the anterior part of the cervix before I could remove the main tumour As there was a considerable amount of shock I ordered a quarter of a grain of sparteine to be administered in a beef tea enema every three hours. There was but little sickness and flatus began to pass naturally 30 hours after the operation. Urine was secreted freely and in 48 hours the sparteine was discontinued, as the pulse became distinctly intermittent, and strychnine and digitalis were given instead There was no trouble with the bowels and when I last heard from the patient, 15 months after the hysterectomy, she was free from any signs of intestinal obstruction. The troublesome complication and the consequent prolonging of the operation caused me all the more anxiety as the patient had a weak circulation and was subject to attacks of fainting during the period, even before much blood had been expelled The sparteine seemed to act well, but I watched its action, as I know from experience that it is apt after a time to cause intermittence of the pulse

In conclusion, it is certain that adhesions are rare in fibroid disease, that when they occur they are not specially associated with any particular variety of that form of tumour or with any other complication to which it is subject, that, on the other hand, they are sometimes a manifest result of previous incomplete or exploratory operations, and that they more often involve the omentum or intestines than the parietal peritoneum

POST OPERATIVE ILEUS.

Most writers experienced in hysterectomy record instances of this fatal complication and one has occurred in my own practice. Sometimes it is simple in character A band of lymph connects the intestine to the stump of the uterus, the stump being in a normal condition so far as healing is concerned, then obstruction occurs, purely mechanical. Still, though Olshausen reports two such cases in his own practice,[8] I suspect that as a rule, obstruction is more often connected with septic changes I will not dwell on the "raw surface" question The dangers of a raw surface on a thick ovarian pedicle have been exaggerated The practice of sewing the edges of the pedicle over the surface with continuous or interrupted sutures is in itself not without danger The foreign bodies used as sutures may be sources of sepsis or other evils and the distal part of the stump may slough after this process of suturing Nor, when it does occur, is obstruction necessarily due to adhesion to the raw surface. Dangerous adhesions may be contracted by the thinnest ovarian pedicle with a very narrow raw surface, and in cases of adhesion the intestine has been found fixed to the side of the pedicle and not to its raw extremity, as in Spencer Wells's classical example.[9]

In retro-peritoneal hysterectomy there is no transfixion and therefore no distal part of the stump as in the ovarian pedicle. I must note in drawing this distinction that some operators, such as Penrose and Howard Kelly,[10] treat the ovarian pedicle without transfixion, they tie the ovarian and uterine vessels separately, leaving the membranous interval free I believe that this practice is in many cases excellent, but it is not quite safe when the pedicle is large. In retro peritoneal hysterectomy, I repeat, there is no distal end and in panhysterectomy there is no stump at all, but ligatures are applied to the peritoneum and to the upper part of the vagina. Obstruction is rare after both these operations for removal of the uterus. Under unfavourable conditions, however, inflammatory changes may render adhesion of intestine very possible. The uterine stump must be handled as little as possible and ligatured as little as possible, whilst the serous coat must be lightly sutured over the muscular tissue This practice is correct for a uterine stump which cannot shrink so rapidly as an ovarian pedicle and is not transfixed by a ligature. Distal ends do not bear foreign bodies, but as I have just observed there is no distal side of a uterine stump As to other considerations about the suture of the peritoneal layer of the flaps, I have referred to them in speaking of the management of capsules

At all events, to return to our subject, experience shows that the ligatured and sutured hysterectomy stump fares well as a rule if the sutures and ligatures be carefully and gently applied But Zweifel warns us that clumsy ligaturing and rough handling of the stump greatly increase the risks of exudation and consequent intestinal adhesion.[11] Unfortunately, certain stumps cannot bear the most gentle handling, whilst the patient's reparative powers are often at a low ebb owing to anæmia from hæmorrhage or visceral complications Hence a certain amount of parametritis is observed in many cases after the removal of a big bleeding fibroid from a sickly woman and exudation not easy to define by clinical research, probably occurs in such cases along the line of peritoneal suture. Such changes favour adhesions

[8] Die Abdominalen Myoma Operationen Veit: Handbuch der Gynäkologie vol ii p 759 Olshausen adds two interesting cases of ileus after ovariotomy (pp 760 761)

[9] Ovarian and Uterine Tumours 1882, pp 426 427 The coil of intestine almost surrounded the sides of the pedicle

[10] Gynæcological Surgery vol ii, pp 24 25

I will now record the only instance in my own experience of ileus after hysterectomy and the observations which I have just made will serve to explain how it developed.

The patient was a single woman, aged 36 years, subject to great pain in the left iliac fossa for over a year There had been no hæmorrhages but her health was very feeble. The pain was caused by the presence of a large fibroid which filled the left side of the pelvis, extending a little above the brim. The growth sprang from the cervix, pushing up the uterus, the sigmoid flexure ran on its surface. There were other fibroid outgrowths, including one in the ovarian ligament, described elsewhere. Enucleation proved difficult as the cervical growth was bilobed and one lobe lay deep down in the parametrium. The capsule, made up of the left broad ligament, required many ligatures as did the thick uterine stump The right appendages were left behind This operation was performed on Dec. 10th, 1901. Evidence of sepsis, of uncertain origin, set in within a few days and obstruction came on gradually The point of importance and interest in the after history of this case was the difficulty of diagnosis of pseudo-ileus from true intestinal obstruction. The pulse grew very rapid and weak, and yet flatus passed freely I feared, however, bacillus coli infection where flatus often passes even when the patient is moribund[12] On the ninth day a great quantity of liquid fæces was brought away by the aid of turpentine enemata and the distension subsided. Within 24 hours, however, vomiting set in and I found that it was distinctly fæcal. Without delay I performed an abdominal section on Dec 19th Notwithstanding the septic symptoms and the feebleness of the patient the abdominal wound was firmly united. The obstruction was far above the sigmoid flexure, it consisted of a volvulus of the small intestine and immediately below it a knuckle of ileum adhered to the right side of the stump of the uterus The small intestine was deeply congested, its coils adhered, and there was turbid red serum in the peritoneal cavity I flushed out the peritoneal cavity with saline solution after setting free the adherent ileum. Unfortunately, the patient never rallied from the shock of the operation and died two hours after being returned to bed. There was a sloughy appearance about the stump of the cervix at the point of adhesion. This accounted for certain unfavourable symptoms seen during the first week—bad pulse, high temperature, and an unfavourable aspect. Pseudo ileus is a common complication of septicæmia and so I was deceived by the manifest septic symptoms The vomiting, fæcal from the first, came on late I operated immediately after detecting it, but the patient was by that time in a very unfavourable condition

In uncomplicated acute mechanical obstruction, as in Olshausen's cases, the symptoms are as a rule quite clear The more or less acute pain and the characteristic vomiting accompanied by quick pulse but no elevation of temperature, are very different from the combination of symptoms characteristic of the pseudo-ileus of septicæmia and septic peritonitis. The surgeon is not likely to delay opening the abdomen in an acute case. On the other hand, the more I see of complicated cases the less sure do I feel about pseudo-ileus and about the prophylaxis of intestinal obstruction in general. Secondary operations for obstruction where there is fever and where passive distension has been distinct before vomiting sets in are highly unsuccessful. Treatment by turpentine enemata, nutrient enemata, the wearing of the rectal tube for about 20 minutes before each enema, and judicious stimulation have saved numerous cases of passive distension with irregular vomiting and fever When, as in my case, this condition masks distinct mechanical obstruction it is often very hard for the surgeon to decide what to do Promptness in operating is the essential in acute obstruction. Deliberation and certain therapeutic appliances are the essentials in pseudo-ileus But we may be much embarrassed by a mixed case. Lastly, there is no absolute prophylaxis against mechanical obstruction The ovarian stump the uterine stump, and the ligatured ridge of peritoneum left in the floor of the pelvis after panhysterectomy may all be the seat of adhesion Even when unnatural prominences may be reduced by surgical ingenuity to a minimum, which we have certainly not yet attained, still the danger of acute obstruction will not even then be passed. Irritated serous surfaces and above all omentum always tend to adhere to what is next to them, and occasionally they fix themselves in such a way as to insure trouble with adjacent intestine In one case of fatal obstruction after removal of inflamed appendages I found a coil of ileum twisted tightly around a tense cord of omentum which adhered to the fundus of the uterus. The appendages had been removed a week previously In opening the abdomen in cases where others have already operated I have repeatedly found omentum adherent in all directions and not rarely full of holes, and I have come across small intestine hanging from the parietes, sometimes with a little diverticulum due to dragging on the adhesion. Yet in these cases there was no history of obstruction. What I have seen, others I find have observed also, and when we say that obstruction is remarkable it is really its rarity that is the feature most worthy of remark After hysterectomy obstruction seems relatively rarer than after ovariotomy, but statistics are not quite clear as to this point Oöphorectomy for inflammatory disease is more liable to be followed by this complication owing, I suspect, to the unhealthiness of the stump, it being never free from inflammatory elements Removal of normal ovaries for checking the growth or bleeding of fibroids is said to be often followed by obstruction, as the stump of the pedicle projects from the surface of a firm fibroid tumour usually more or less fixed and thus may lie in contact with the same coil of intestine for days This theoretical explanation is plausible, yet though we very often performed this operation at the Samaritan Hospital ten years ago, and not always with perfect success as to its aim, I cannot trace one case where obstruction occurred I know of one instance of acute obstruction following several months after retro-peritoneal hysterectomy and it was successfully relieved by the original operator But it seems certain that this grave complication is rare after hysterectomy The stump sinks down into the pelvis and undergoes atrophy After an ovariotomy the uterus drags on the stump of the pedicle which stands up in the middle of the pelvis in a position more favourable for contracting adhesions

RUPTURE AND HERNIA OF THE ABDOMINAL WOUND

One of the disadvantages of extra peritoneal hysterectomy with the application of the serre-nœud was the frequency of infection of the abdominal wound The process of cicatrisation was thereby much impeded and yielding of the wound followed by prolapse of coils of intestine was not rare. This complication is even more dangerous than it is inconvenient in such circumstances. When sepsis has played no share in the accident it is otherwise, for when a weak but uninfected wound yields intestine may come out and even lie in folds of dirty underlinen for hours before reduction without fatal results[13] In the retro-peritoneal operation and in panhysterectomy rupture of the wound from septic influences is almost unknown. So many of us perform hysterectomies and are obliged to make long incisions, often in subjects weakened by anæmia, that we must think about the strength of the cicatrix and the risks of the development of hernia. Experience shows that the cicatrix is usually strong enough not to yield and to allow the bowels to prolapse, provided that the sutures if meant to be removed are not taken away too early, or if left are strong enough to hold the structures around the wound firmly till the cicatricial tissue is enough organised to do so The constitution and the habits of the patient are two ever uncertain factors I cannot dwell on the relative merits of a single row of interrupted sutures including all layers of parietes and of sunken sutures absorbable or unabsorbable. continuous or interrupted, uniting the layers separately Different surgeons of like authority and experience are by no means agreed about this question. In some cases I find that very bad hernial protrusions follow the older and simpler method, but as I pointed out many years ago the complication is often the result of taking up too much of the peritoneum so that two opposed layers of serous membrane project forwards between the more superficial structures, effectually preventing their union. A hernial pouch is easily developed in this manner

[12] See Vautrin's valuable article on Colibacillary Infection after Hysterectomy Revue de Gynecologie et de Chirurgie Abdominale, November-December 1901

[13] Cestan Quatre cas d'Eviscération Post-opératoire Spontanée Toulouse Medical Nov 1st 1900 p 249 A case where prolapse of a foot of small intestine through a gauze drainage-track occurred on the ninth day with no evil results is recorded in my article on Chronic Serous Perimetritis simulating Cyst of the Ovary &c., *Journal of Obstetrics and Gynæcology of the British Empire* vol. i. p 265.

On the other hand, hernia of the cicatrix is by no means unknown after suture of the parietes in layers More than one operator of experience has found out that truth Septic changes may occur around a sunken unabsorbable ligature, the patient feels a little pain some time after the operation, and an abscess forms, leaving a weak spot. I have observed this complication twice in cases where I had been the operator and another instance is recorded where a patient was admitted into hospital for a stitch abscess a year after ovariotomy by a distinguished authority[14] There is, on the other hand, evidence that catgut is too soon absorbed to allow of firm union, excepting some samples of chromicised gut which are very slowly absorbed and thus have the disadvantages of wire and silkworm gut. My suspicions are confirmed by three cases recently reported by M Recours of Bordeaux in an instructive thesis based on 62 cases of rupture of the wound and prolapse of intestine[15] Three cases are included where rupture occurred in the practice of one surgeon and they are worth considering for a minute or two, since where three wounds yield during convalescence and allow intestine to prolapse, many more sutured in the same manner must be so weak as to become inevitably the seat of rupture In all three cases catgut was applied to the muscular layer and horsehair to the integuments The first patient was a man, aged 58 years, he underwent pyloro gastrectomy for cancer The wound yielded on the ninth day, but healed after it was sutured again, as happened in the two other cases The second patient was a man, aged 50 years, with chronic catarrh, the wound gave way on the twelfth day after gastrostomy The third case directly concerns us. The patient was a woman, aged 50 years, subject to uterine fibroid. She was cachectic, presumably from anæmia. Panhysterectomy was performed, the wound gave way, apparently without any violent effort, on the tenth day Thus Recours rightly concludes that catgut, which is absorbed, or at least becomes practically useless within a week, will not allow time when the patient is feeble for the development of cicatricial tissue strong enough to bear by itself abdominal pressure increased by coughing or voluntary muscular efforts.

Into the statistics of hernia of the abdominal wound after hysterectomy I do not propose to enter, as I know not of any on which we may rely In the operative results of one surgeon the latest cases fare nearly always the best, as he was most experienced when he performed his later operations and a life saved is a clear success directly after fair and evident convalescence. But it is otherwise when the strength of the cicatrix has alone to be taken into account In 100 successful abdominal sections performed within 12 months there may be no case of hernia of the cicatrix, or rather no case where that complication has become advanced enough to be detected by the patient. But three years later there will assuredly be more than one hernia in the series

CANCER OF THE STUMP OF THE CERVIX, THE ALLEGED MALIGNANT FIBROID

Most of the subjects discussed in this lecture are illustrated by cases in my own experience. I am glad to say that I have never observed cancerous degeneration of the stump after retro-peritoneal hysterectomy in my own practice. Thus I am compelled to depart from the rule which I have endeavoured to maintain in respect to other matters of interest pertaining to uterine fibroids and their treatment. On the other hand, whilst I have refrained from speaking of subjects which happen never to have come under my personal observation, I feel bound to make an exception in regard to malignant changes in the cervix. Whilst I advocate a certain operation I am not justified in turning my back on the fact that others have shown that it is sometimes followed by evil results Therefore, in respect to cancer of the cervix I feel bound to review the experience of others. In the first case we must make sure of the nature of these degenerations of the cervix Is the "cancerous" stump always carcinomatous? On looking into the literature of the subject I find that sarcoma of the stump has been mixed up with carcinoma. This is a grave error In speaking about fibroids, as I have already endeavoured to explain, pathology need not trouble us much, as we take it for granted that the tumour is a fibro-myoma When there is a question of malignancy the case is completely altered. Sarcoma of the cervix is a very rare disease, so is sarcoma of the uterus, but it is not always easy to recognise sarcomatous degeneration of the uterus, so that sarcoma of the stump after hysterectomy may imply that there were sarcomatous elements in the entire uterus when it was amputated. Cancer of the cervix is very common and if it develops after hysterectomy can we be always certain that the germs of the disease were not present before the operation? Can we be certain that the operation caused the cancerous degeneration? Lastly, may not any method of operating which insures as much as possible the maintenance of the nutrition of the stump favour, on that very account, the development of cancer? Or does the truth lie in the opposite direction—that is to say, may not a method which insures ultimate atrophy of the stump favour malignant degeneration?

I will first dispose of the cases of sarcoma of the stump which have been mixed up with the carcinomas. I have found three distinct cases, but in the first let it be remembered that the uterus was removed by the old extra peritoneal operation It is recorded by Wehmer[16] The tumour was a fibro myoma weighing 16 pounds and the patient was 44 years of age Now let us mark that sarcoma developed a few months later in the *scar* and rapidly diffused itself over the peritoneum. It is not clear how far the cervix was involved and the malignant disease might well have originated in the parietes adjacent to the stump The second case is reported by Menge[17] Sarcoma developed in the stump after removal of a cystic fibro-myoma of the uterus 11 pounds in weight But he admits that the uterine tumour was registered as an "innocent" fibroid on the strength of its naked eye appearances ("*grossanatomisches Aussehen*") Hence Menge had his doubts. The third case of sarcoma of the stump was related by Dr Stone of Washington in a discussion to which I shall presently refer The sarcoma was discovered in time before the patient left hospital, this fact is sufficient to show that the uterine tumour was in all probability sarcomatous The cervix was subsequently removed with success.

Thus there are three fairly reliable cases of "cancer" of the stump which were really sarcomata. We cannot feel sure that others described as "cancer" were not also sarcomata In one of the three cases actually recognised as sarcoma the modern retro peritoneal operation was not performed and the sarcoma may have originated in the parietes, in the second there was no microscopic examination of the uterus when it was removed, whilst in the third the probability that the uterus itself was sarcomatous is extremely strong We cannot dismiss these cases of sarcoma without dwelling a little on malignant degeneration of fibroids, though a full discussion of that grave subject would here be quite out of place. Continental authorities claim to have discovered that sarcomatous change in a fibroid is not rare, but they rely much more on microscopical appearances than on clinical histories. Thus as long ago as in 1888 Martin detected four cases in a series of 205 operations for the removal of fibroids of the body of the uterus[18] As recently as last March Ulesko-Stroganowa declared that she found that ten out of 100 cases of fibroid examined by her were malignant, a proportion utterly at variance with clinical experience.[19] She makes out that this "malignant" fibroid is a true leiomyoma, like any other fibroid, the muscle cells altering their form until they become polymorphic, yet in all cases the polymorphic cells can be traced back to plain muscle. The tumour which I described in 1889 was probably of this class[20] Never since that date

[20] Myoma of the Uterus becoming Sarcomatous Transactions of the Pathological Society vol xli 1890 p 206 My conclusions (*Ibid* p 212) practically signify that the tumour in question was a malignant myoma developed from the elements of plain muscle cells which had never advanced beyond their embryonic stage

have I come across a true malignant fibroid and I regret to say that I was unable to trace the patient in that solitary case after her convalescence. I cannot find many records of malignant fibroid in the United Kingdom, though the attention of the medical world has been so much turned towards uterine tumours of late years. Nor do the foreign observers furnish us with after histories of their cases. It seems clear that in most instances the tumours of the kind described by Ulesko-Stroganowa are clinically innocent and that the changes in the muscle cells, formidable in appearance, are not malignant after all. Many of her colleagues were of that opinion when she discussed her researches before a society.[21] Dr. Lockyer, to whom I am indebted for his careful examination and preparation of many of the specimens which illustrate these lectures, has recently turned my attention to an example of "malignant fibroid" which he intends to report in full. Most unfortunately the patient died after the operation, which was performed by an experienced surgeon. Two points of interest must be noted in respect to this case. Firstly, the tumour consists of large well circumscribed growths, purely sarcomatous in the midst of a pure myoma, so that it is not certain that it corresponds with Ulesko-Stroganowa's cases. Secondly, what is yet more important for our purpose, I cannot see how the operator could have taken the fibroid for a malignant growth. Had the patient lived of course malignancy would soon have been manifest in the remains of the cervix. But then the case would have been an argument, I admit, in favour of panhysterectomy, but not an example of malignant disease developing in a stump of which the tissues were healthy at the date of the hysterectomy. I turned attention to this source of fallacy in relating Menge and Stone's case. The same must be said of Dr. Herbert Spencer's cases read at the Manchester meeting of the British Medical Association last August.[22] In two cases of retro-peritoneal hysterectomy the tumours were indistinguishable from fibroids and were not known to be sarcomata until some months after removal; the patients ultimately died with secondary masses in the pelvis. This experience is no doubt a plea in favour of panhysterectomy but there was no sarcomatous degeneration of the stump of a previously healthy cervix. It is remarkable that one operator should have had two cases of so rare a disease as sarcoma of the uterus with full clinical proof of malignancy within a very few years.

Thus there is such a thing as malignant fibroid and it must be taken into account in association with degeneration of the stump. We must further grant that a malignant fibroid is a sarcoma. Cancer of the fibroid uterus means carcinoma of the uterus coincident with a myoma, a grave complication to be duly borne in mind in association with the carcinoma of the stump which we must now consider, but a 'cancerous fibroid' is not clinically any more than pathologically the same thing as a true sarcoma of the uterus developed from muscle cells or their elements.

Having duly weighed all these considerations about sarcoma, we are at length free to discuss cancer of the stump of the cervix, true carcinoma, which has undoubtedly been observed after retro-peritoneal hysterectomy. The most interesting summaries of clinical evidence which have recently appeared are to be found in Thumim's monograph on the operative surgery of the gravid uterus[23] and in a discussion held this year at the annual meeting of the American Gynæcological Society on the Relative Advantages of Complete and Partial Hysterectomy.[24] Thumim considers that the 15 reported cases of malignant degeneration of the stump are arguments against retro-peritoneal hysterectomy and favour panhysterectomy. But he includes the two sarcomas (Wehmer and Menge) which we have put aside and candidly admits that in two of the cases of carcinoma malignant degeneration of the cervix possibly existed when the uterus was removed. One of the doubtful cases was in Freund's practice; the second was reported by von Erlach in a discussion on Savor's case, to which I shall presently refer. Von Erlach, like Menge in his report on the sarcoma, was not sure that there was not cancer at the time of the hysterectomy; the uterine tumour was necrotic and was not carefully examined. I think that another case, included in Thumim's series of 15, is more than doubtful in the same respect. Schenk[25] is the reporter. The patient, I find on referring to the original report, was 57 years of age, and the uterus, as big as a fist through the growth of a tumour, was removed on account of bleeding for two months, with pain and emaciation. The operation was performed in December, 1897; sanious discharge was soon observed and in April, 1898, the stump of the cervix was found to be cancerous. The patient died four months later. Comment would be superfluous on such a case. Savor's case[26] is nearly as suspicious. The patient was 48 years of age when the uterus was amputated and the cancerous stump was taken away when she was 52 years old. The germs of cancer very probably existed at the time when this elderly patient underwent the operation. Thumim quite justly turns his reader's attention to a case where Landau removed a fibroid uterus by panhysterectomy from a woman, aged 44 years. When the uterus was examined after the operation cancer of the cervix was detected, a complication which had not been previously recognised. Had the cervix been left blame would have been attached to the "incomplete operation." All these cases show that statistics are misleading and when the disease develops in the cervix after the operation there is no clear evidence that the operation was the cause of the cancer. I speak elsewhere of a case in Martin's statistics where cancer of the cervix developed after double ovariotomy for tumours of an innocent type. Nobody would consider that the ovariotomy caused the cancer of the cervix.

The discussion in America to which I referred is worth attention. Noble, Cushing, and Janvrin considered that malignant degeneration was very rare. Cushing distinctly stated that the cervix has a certain physiological function of its own that is of value and on that account it should not be removed when hysterectomy is performed on a young woman. This consideration is much more important, in Cushing's opinion, than the ultimate chance of cancer developing in the stump. His theory appears related to Abel-Zweifel's which I took into consideration when speaking of the treatment of the ovaries in hysterectomy, but the German authorities insist on a retention of a piece of the uterine mucosa above the level of the os internum. Cushing is silent about this qualification and as I have already stated American operators amputate the cervix below the os. Noble of Philadelphia has observed cancer of the cervix in only one out of 300 hysterectomies in his own practice and in that case it was present before the operation. The case of sarcoma of the cervix recorded by Dr. Stone of Washington has been already mentioned. It is clear that when part of the cervix is left that part may become cancerous, but this complication is rare and there is no evidence that the operation causes it. So far the advocates of panhysterectomy may make use of the complication in question, but there are other considerations which favour the supra-cervical operation. On these, however, it is not to the point for me to dwell.

The last consideration relative to malignant changes in the stump is of considerable interest. Such changes, it is evident, occur occasionally. May not any method of operating devised to maintain the nutrition of the stump favour on that very account the development of cancer? I refer, of course, to the preservation of the ovaries in hysterectomy, a subject which I have already discussed at considerable length. Or does the truth lie in the opposite direction? That is to say, does an atrophic stump of the cervix tend to become carcinomatous just as cancer usually develops in the cervix when the uterus is becoming sexually aged? The truth remains unknown. The maintenance or the limitation of the nutrition of the stump must play a part in the development of cancer, but as to which condition favours, and which tends to avert, malignant changes we know nothing. We saw that there is great uncertainty as to the effect of removing or leaving the ovaries in any one case of hysterectomy. We also saw that observers do not agree as to the effect of leaving or removing part of the uterine body as well as the cervix In short, we are far too ignorant about essential points to be able to solve this question There must be a solution, but at present we lack even bare clinical evidence. We know that the preservation of the ovaries in hysterectomy, as a rule at least, favours the continuation of a modified menstruation and as a rule softens the artificial menopause. Unfortunately I find that in the records of carcinoma of the stump the treatment of the ovaries is seldom if ever noted. None of the authors lay any stress on the matter I have only succeeded in obtaining evidence about the ovaries in two cases, both recorded this year by M. R Condamin of Lyons.[27] That writer, like his predecessors, makes no mention of the ovaries, but he kindly took the trouble to reply to a letter which I wrote to him asking for the necessary information. He stated that at the time when he operated on the two patients he always left at least one ovary The evidence of two cases, however, is insufficient, especially in one instance, for the first patient was 58 years old and malignant disease appeared as a bleeding fungous mass in the stump a year after the hysterectomy It might well have existed at the time of the operation The second patient was 40 years of age and the malignant changes in the stump were detected by accident four years after the hysterectomy during an operation for hernia of the abdominal cicatrix. Pain, hæmorrhages, and fatal cachexia quickly followed Thus it is clear that we want more light thrown on this question Let all operators faithfully record the treatment of the ovaries and the nature of the uterine flaps in every case of hysterectomy for fibroid disease. If there be clearly any distinct advantage in one line of treatment—I mean clear evidence of relative immunity from malignant changes—let us adopt that treatment, for there is great weight in Cushing s argument in favour of retaining the stump of the cervix, but if no method of treatment secures the cervix from degeneration, and if better evidence than is at present at our disposal can establish a causal relation of the preservation of the cervix to its malignant degeneration, then we may seriously think about adopting panhysterectomy to the exclusion of the less complete operation.

---

[21] Loc. cit., October, p. [illegible]. Fenomenoff considered her percentage of malignant cases too high. Levinovitch remarked that young plain muscle cell was hard to distinguish from connective tissue new growth. Redlich was of a similar opinion. Raschinsky remarked that in one case reported by Ulesko-Stroganowa as malignant there was no evidence of malignancy outside microscopical appearances. See also discussion in the Transactions of the Obstetrical Society of London, vol. xli., 1899, p. 369.

Danger of pushing a Fibroid out of the Pelvis

Pushing up an impacted fibroid is never a thoroughly safe proceeding It is specially dangerous during pregnancy, and we must remember that that condition may be overlooked in a young woman where metrorrhagia is present and simulates menstruation. The impacted fibroid is usually firmer than the gravid part of the uterus and not rarely very much harder, the danger of pushing a hard against a soft mass is evident. I exhibit a very instructive preparation, it was a fibroid uterus which I removed during pregnancy Some of you have seen it before, the full history is published in The Lancet[28] and there is a fine engraving of it in the forty third volume of the Transactions of the Obstetrical Society (p 178) I watched the development of the pregnancy for over six weeks The lower mass became fixed in the pelvis Reduction would have been very dangerous. Observe the soft uterus, once containing a fair amount of liquor amnii. The mass beneath it is extremely hard, the growth above it is at least much harder than its own tissue It lies like an orange between two stones. As the impacted mass caused pressure symptoms, so that it was inadvisable to wait till term and do a Cæsarean section, I removed the uterus

I know that a hard mass in the pelvis associated with a pregnant uterus is naturally supposed to be a fibroid and when impaction is threatened many practitioners try to push the mass out of the pelvis Experience, however, teaches us that a small tense ovarian cyst pressed down into the pelvis may feel very hard when the hand contrasts it with the soft pregnant uterus This fact must be remembered, as rupture of an ovarian cyst in pregnancy is serious. I exhibit a cyst from a case in point which I recorded in full[29] last spring Before the pregnancy the patient had noticed no symptoms of any tumour, attacks of severe pain set in during the fourth month, and on examination a mass was found occupying Douglas s pouch and the left fornix. It seemed absolutely fixed and was very firm, but owing to its position under and behind the pregnant uterus satisfactory bimanual palpation was not practicable, even under an anæsthetic. Gentle attempts to push it up were made under chloroform Several of my colleagues at the Samaritan Hospital examined the patient with me on that occasion and we all agreed that the firm tumour was probably ovarian, yet possibly might be a fibroid, as in the other case. We were certainly prudent in avoiding firm or continuous pressure I made an exploratory incision and found on raising the uterus out of the abdominal wound that the tumour was a small pyriform cyst of the right ovary displaced backwards and entirely to the left. It was jammed in the pelvis behind the uterus. Its pedicle, twisted two turns, was stretched tightly across the back of the uterus The left ovary lay both above its fellow and above the pelvic brim The cyst was removed with the greatest ease, I operated in the fifth month and the pregnancy went on to term. I think that these two specimens are a good object lesson, teaching us the perils of trying to push a firm tumour out of the pelvis during pregnancy I was careful about handling the pelvic swellings and so the patients were preserved as well as the specimens.

In concluding these remarks about pushing up pelvic tumours during pregnancy I must once more insist on the difficulty of diagnosis in these cases where the tumour can seldom be explored bimanually A swelling resembling a cystic fibroid might prove to be a hydatid cyst. Franta, who has written a valuable monograph on hydatid cysts in pregnancy, labour, and the puerperium,[30] notes that only in one recorded case could the cyst be successfully pushed up above the pelvis during labour I doubt if anybody would care to push up a hydatid cyst, if he had diagnosed it, in any circumstances. Great care must also be taken when attempts are made to push up a fibroid even when the uterus is evidently not gravid. The fact of impaction is only certain when the operator knows on very reliable evidence that the mass fixed in the pelvis was recently free and moveable Pushing a broad ligament fibroid might entail serious consequences

In conclusion, Mr President and Gentlemen, I must heartily thank you for the patience with which you have listened to me I have endeavoured to turn attention to several unsolved factors relating to fibroid disease and have dwelt on two themes which many of us believed to be defunct until it was shown last summer that they were only in a state of suspended animation You will now understand why I have avoided disquisitions on the innocence of fibroids, the necessity for surgical interference, and the best kind of operation These matters have been freely discussed of late by able advocates and opponents, so freely that I understand that the profession is getting tired of discussions which are not likely to lead to any solution I must specially thank my friend and colleague, Dr Cuthbert Lockyer, for the pains which he has taken to prepare a number of specimens which I have used during these lectures for purposes of demonstration.

SOME THOUGHTS AND OBSERVATIONS REGARDING APPENDICITIS, ESPECIALLY WHEN APPEARING IN ITS ACUTEST FORMS

By J A MacDOUGALL, M D, F R C S Edin,
CONSULTING SURGEON TO THE CUMBERLAND INFIRMARY SURGEON TO THE FRENCH PROTESTANT HOSPITAL AT CANNES

Age—the process of growing old—has many notable disadvantages but it has also its compensations, one of which is that in clinical work one can contrast a somewhat distant past with the vivid present and take note of any changes that may have occurred in the vital manifestations of disease And that they do, and indeed must, arise, I have no manner of doubt for as many diseases depend largely upon environment and social states for their development, and as permanency in these conditions is rare, so must changes arise in the maladies they promote

[30] The complete essay Kystes Hydatiques pendant la Grossesse, l Accouchement et les Suites de Couches " is published in the Bohemian language (Prague 1901) with a summary in French The clinical reports were published in the Annales de Gynécologie et d Obstétrique, March 1902.

Appendicitis is no new disease, but that it is a disease largely on the increase, both as regards the number of its victims and its severity, is my conviction. And here are some of the reasons for this belief. 30 years ago and more, when I was a student in Edinburgh, one saw from time to time cases of typhlitis and perityphlitis, marked by the signs and symptoms of a localised peritonitis, and above all by the presence of a tender tumour in the right iliac fossa. Occasionally the tumour underwent the process of suppuration—the abscess was opened and as a general rule convalescence followed None of these patients died and the very able physician whose clinical clerk I then was, the late Dr Warburton Begbie, said of them, "They don't die" This early and happy experience was supplemented by nine years of arduous work in a manufacturing town, in which the population was largely composed of those whose age predisposed them to trouble in the appendix, and here, again although the disease was ever and anon before me, recovery was the rule—*I met with no fatality Moreover, I did not* meet with the cases of fatal so-called idiopathic peritonitis which are now believed by many to have hidden errors in diagnosis,[1] although one or two patients who died from intestinal obstruction very possibly as I shall endeavour to show later, really perished through trouble in or around the appendix. It was not until 1887 that I met with lethal appendicitis, and then, strangely enough, within a very limited time I saw four cases, all of which were quickly fatal. Two of these patients I operated upon, in both foreign bodies were present a gall stone in one and an orange pip in the other in both the appendix was perforated, and the cavity of the peritoneum contained much pus This naturally drew my attention very forcibly to this morbid condition, and as the years have run this interest has not diminished, for I have seen a steadily increasing number of cases and also a very notable increase in their severity And mine is no singular experience. Following the publication of the last Cavendish Lecture by Sir Frederick Treves in THE LANCET[2] there appeared in its columns some valuable correspondence bearing upon appendicitis and among other letters was one from Sir William T. Gairdner,[3] who is universally recognised as one of the ablest and most accurate of clinical physicians, both as regards his facts and his statement of them, and here is something of what he wrote "The first point that appears to require notice in view of more recent researches is that the case in 1884 was absolutely the first case that I could find in my own records of a fatal result of perityphlitis during the 10 years in which the Western Infirmary had been open A careful inspection of the records of the pathological department discovered two more such cases, as well as two others which had been sent in from without for examination On the whole, and speaking with such diffidence as is necessary to allow for lapses of memory I am inclined to think that this was the very first fatal case that had occurred to myself personally either in hospital or consulting practice" Five fatal cases occurred in a great institution in the course of 10 years while during last year alone (as the medical superintendent, Dr D J Mackintosh, M.V O, courteously informs me) there occurred in the same institution 64 cases of appendicitis which demanded operation, and of these nine were fatal. Again, in the correspondence referred to is a communication from a well known practitioner, Dr W J Tyson[4] of Folkestone in which he says "I was at Guy's Hospital some 25 years ago and during my stay there of six years I never saw a case of appendicitis operated upon"[5] The experience of the students of Guy's Hospital must be very different to-day My friend Dr W Jeffrey of Jedburgh, a very able and observant physician, writing to me on this very matter, says "I know that in the old days, 35 to 40 years ago, when I sat at the feet of Warburton Begbie, whereas these cases of 'limited peritonitis' (as they were then called) gave one no anxiety—one looked forward to them one and all doing well—it is now very different. Every one of them makes me anxious and frequently, as the event proves, with all too great reason" These are, however, only individual experiences and we know how these may vary, but the same story is told and, as would be expected, even more emphatically, by the records of some great hospitals Take, for instance, those of St. Bartholomew's Hospital, and in order to avoid a very large mass of statistics I have selected for comparison the three oldest hospital reports which to me are available and the three latest. How they work out is shown in the following paragraph.

In none of the surgical reports for 1882, 1883, and 1884 is there any reference to typhlitis or perityphlitis or to operations in connexion with either condition. It is true that under the heading of "Abdominal Section" in 1883 four operations were performed unsuccessfully in early life (in two of which cases the patients were under five years of age) and it is possible that harm in the appendix may have played a part in some of them but there is no certain indication on this point. That under the title of 'Abscess (Diseases of Connective Tissue)' a certain number of cases may be concealed is very probable, but here, again there is no sure light. Turning to the medical reports the following is the result During the three years under consideration there are recorded under the title of Perityphlitis" 41 cases with two deaths and of Acute Peritonitis" 38 cases with 21 deaths The analysis of these deaths is interesting for in 1882 of the five patients who died only one was under the age of 30 years and while this in no wise excludes the possibility of some of the others having suffered from trouble in the appendix in the absence of all definite knowledge the fact is worthy of notice. In 1883, of the 13 cases of peritonitis which proved fatal only two were found to be due to appendicitis while in 1884 of the three patients who died only one had assuredly this association The gross results thus are 41 cases of perityphlitis with two deaths and 38 of acute peritonitis with 21 deaths only two of which were certainly associated with lesion of the appendix while it is possible that six others may have been. Add to these a fatal case occurring in 1884 under the title 'Perforation,' in which an opening in the appendix was found and we have a mortality of 11 in a total of 79 cases.[6] The 15 years that elapse between 1884 and 1899 bring a new recognition of the importance and of the treatment of appendicitis In this period it has become a malady with which the surgeon has more or less to deal. The term typhlitis' disappears from the nomenclature and under the terms 'appendicitis' and 'perityphlitis" is the disease recognised. Its magnitude is further marked by divisions which increase in number as its various pathological and clinical manifestations are acknowledged We find acute and chronic appendicitis without external suppuration and this in surgical as in medical wards is a comparatively mild malady but when the acute form is attended by suppuration, when it is in association with the occurrence of gangrene and with perforation of the organ its gravity grows great. In 1899 there were in the medical and surgical wards 97 cases in all, with a gross mortality of 10 but 54 of these demanded operation In 1900 there are tabulated in the medical and surgical departments 102 cases with 16 deaths, and in these 102 cases operation was necessary 80 times In 1901 we find that there is the increasing number of 122 cases, that of these 12 patients died and that it was necessary to operate on 83 patients

In the first three years that have been considered there were 79 cases (typhlitis *and peritonitis*) with 41 deaths, a considerable number of which may, however, have been unconnected with the appendix, while in the later years there were 321 cases (perityphlitis and appendicitis) with 38 deaths. The thought, however arises that in the increased number of the sick attending the hospital may be found the explanation of this apparent increase, but that this is not so is indicated by the fact that while in 1882 there were 4249 patients and only 16 cases of perityphlitis and 20 of peritonitis, in 1901 with 6331 patients there occurred 122 cases of perityphlitis alone.

---

[1] Regarding this point I have heard it frequently asserted that the term peritonitis" not only covered in other years the fatality of appendicitis but that it had its origin almost invariably in lesions of that organ That this may be a very erroneous estimate of pathological possibilities such facts as the following will show In 1883 there died in St. Bartholomew's Hospital 13 patients the subjects of peritonitis and this is what necropsies in nine of the cases revealed—two were due to ulceration of the appendix, one to stricture of the colon one to obturator hernia, one to bursting of a renal abscess one to chronic dysenteric ulceration, one probably to pyæmia, one to carcinoma, and one to fibroma of the uterus and again in a collection of 21 cases of perforative peritonitis collected by Jantz and quoted by Dr W Hale White seven followed perforation of the appendix five perforation of a gastric ulcer three perforation of a typhoid ulcer two hernia, one a rupture of the stomach one a rupture of the intestine one the rupture of a duodenal ulcer and one the rupture of a perimetric abscess.

[3] THE LANCET July 12th 1902, p 103.

[4] THE LANCET July 19th, 1902, p. 183.

[5] Of interest in connexion with this statement is the following by Dr Hilton Fagge: Even when typhlitis presents itself clinically under the guise of intestinal obstruction or of diffuse acute peritonitis I believe that it scarcely ever destroys life if judiciously treated. There may be cases in which a considerable part of the appendix sloughs away and in which death is inevitable But I only know of one fatal case as having occurred within the last five years at Guy's Hospital if I may exclude cases in which death took place a few hours after admission and in which purgatives had been given freely" (Fagge's Principles and Practice of Medicine 1886 vol ii p 175.)

[6] As there is at this period in the reports not the same clear definition that is observable in the latest ones I have classed together peritonitis and typhlitis and their issues, so as to avoid the chance of unwittingly diminishing either the number of cases of appendicitis or their fatality

Two other points in relation to increase in frequency and in severity seem worthy of note. The first is the greatly increased frequency of relapse I can recall a good many cases seen early in my professional life which have since then escaped all similar trouble, but it has not been so with those met with in later years—relapse, if not the rule, has at least become far from exceptional, and it is this tendency and the surgical interference that it demands that make the number of operations on the appendix so much more numerous. The second is the notable way in which in certain families the malady is found As I write this, and without any great effort of memory, I can remember several family groups which illustrate this In one both the father and the mother suffered from the disease, two daughters out of four also suffered and so severely that in one case suppuration occurred and in the other gangrene, in another group the mother was the first attacked, and out of a family of three—two sons and a daughter—two have been its subjects the son requiring operation. Again two brothers in a family of five were attacked, one of whom died rapidly in his second attack, two sisters in a family of four sisters were attacked, one requiring operation and the other remaining now under watchful observation, and in one family of two, a sister and a brother, the sister had one mild attack, the primary one in the case of the brother demanding operation All these having come under my own observation within the last few years can hardly be regarded as fortuitous, and the interest attaching to them is the greater because inquiry affords no evidence of a tendency to gastro-intestinal ailments, or any mortality from such in the immediately preceding generation Even in the sufferers themselves with the exception of one or two of the girls who had been subject to constipation, there was no story of those nervous symptoms of those circulatory disturbances, or of that vicious metabolism to which some writers attach importance as hereditary exciting causes of this disease

With these recorded facts, which I incline to regard as proofs that the disease is an increasing one and that its severity is apt to be greater than it was in other years, my attitude, like that of many others well known to me, has undergone considerable change as regards the larger necessity for operation in cases of appendicitis but I am still absolutely averse to the assertion that the diagnosis of the malady carries with it inevitable surgical interference In the very large majority of cases, the prognosis when the case is under careful medical supervision is a favourable one, but there are certain exceptional examples in which the possible recovery of the patient rests largely with the surgeon To the observant practitioner who has had a fairly large experience of appendicitis such cases are not difficult to recognise—the stamp they bear is a very clearly cut one—but to the man of average experience who has seen many cases get well and who only knows through the teaching of others how tragically some can die there are few more difficult or anxious considerations than the decision as to their management. It is with the endeavour of rendering this difficulty, which was at one time a very personal one and which I know is still a puzzle to others, somewhat easier that I venture to record some of the lessons that have come to me on this point, and as our power of recognising the gravity of a disease when some of its most notable features are absent depends largely upon our acquaintance with it in its truest developments, I detail two concrete characteristic examples of ultra acute appendicitis

CASE 1.—A patient of Dr J W Campbell of Mentone, a man in early middle life had, some six months before the illness in which I saw him and while resident in London, a sudden severe attack of abdominal pain He was seen by one of the best known of English physicians and by an able surgeon their joint diagnosis being one of gall stone colic. Early in the morning of a certain Saturday while in bed he was again attacked by the old pain the character and the situation of which he quickly recognised, and he was seen in the course of a few hours by Dr Campbell. The patient was then suffering severely and a dose of morphia was given him, which brought so much relief that for many hours he was comparatively easy On the Sunday morning the pain returned with increased violence, he vomited, became cold and depressed, and was obviously very ill. Dr S M Rendall, who then saw him with Dr Campbell, agreed with the latter that he had an acute appendicitis and that surgical interference was necessary The same evening at his bedside I met these gentlemen, when his condition was typical of what had befallen him He had an anxious, drawn, pained look, and complained much of abdominal suffering, he had rather quick costal breathing, a slow and very small pulse of 84 a subnormal temperature of 97° F, and a flat, board like, non tender abdomen but one which did not permit of a deep inspiration being taken and the nervous, anxious attitude of a man who felt himself to be gravely ill On opening the abdomen a quantity of milky looking pus made its escape, and when the cæcum was drawn up it was evident that the cavity of the pelvis was full of the same fluid The appendix, enlarged, inflamed, and thickened, presented a large perforation on the inner aspect of its lower third and its mucous membrane was extensively ulcerated Sponges with a strong solution of biniodide of mercury (1 in 2000) were used to cleanse the parts, and a large drainage-tube was placed in the recto vesical pouch Although it was some days before the tube could with safety be removed he made a good recovery

CASE 2.—The patient, a girl, aged 16 years, had in the month of June what was recognised as a threatening of inflammation of the appendix which was alone marked by a single act of vomiting and some tenderness on pressure in the right iliac region, for she had no fever and made no complaint of pain until examination of the abdomen revealed the tender area For this she was most carefully treated by absolute rest and careful dieting and in the course of a week or two she seemed quite well Examined three months later there was not a shadow of evidence of her former slight illness to be detected. In the early hours of a morning at the end of September she awoke with abdominal pain, not very acute in its character for it was much relieved by a hot application, but she shivered, became hot, and felt very ill Seen by a medical man in the morning she was found to have a temperature of 102° F, a quick, peculiarly small pulse, a flushed face, a flat abdomen, with rigidity and dulness over the cæcal region, but with no tenderness and no muscular rigidity beyond this area. As there was a history of some constipation her medical attendant regarded the case as a typhlitis due to a packed cæcum, the apparent dulness supporting this opinion An enema was ordered which acted freely and well, but so comparatively mild was the pain in the abdomen that opium was not thought necessary In the evening the general condition was not improved for the temperature was higher (104°) and the pulse quicker (130), but the patient expressed herself as feeling easier A small dose of opium was given at bedtime and a fairly good night followed. On the succeeding morning the temperature had risen to 105°, the pulse to 150, the previously dull right iliac region had become clear and the muscular wall soft, while there was increase in the area of abdominal tenderness In the late afternoon I saw the patient. She was bright and happy looking, even cheerful when roused, but she was somewhat somnolent—somnolent from that state of euthanasia which happily marks some acute septic processes. Her pulse was fully 150, her temperature was 105° (it had been higher earlier in the afternoon), and the abdomen, not full and not markedly tender, was still moving easily with respiration—indeed, she could take, when asked to do so a nearly full inspiration She made little complaint of suffering had never vomited and the most careful examination failed to give any evidence of intra abdominal effusion Despite the absence of many indications which in the presence of an acute peritonitis are sure guides, there could be no doubt as to the diagnosis here and the abdomen was opened Red distended, lymph-coated intestine and a much infiltrated omental edge at once showed themselves and when the appendix was exposed its colour told the story of its condition. The mesenteriolum cut under the ligature as cheese would cut and the surfaces left were as dry, for every vessel in the mesentery was plugged The appendix when drawn upon separated at its insertion into the cæcum—for it was a gangrenous mass—and left a considerable aperture in the wall of the bowel. This was closed by a double row of Lembert's stitches, the parts were carefully cleansed with swabs, and two drainage-tubes passing into the floor of the pouch of Douglas were so arranged with reference to the aperture in the cæcum that they would command any leakage from the viscus Within 36 hours of the operation her temperature was normal, the drainage tubes, allowed to remain for ten days, were expelled by the process of granulation, and her recovery was uninterrupted

But one cannot always expect to have the picture so unmistakeably drawn as it was in these two cases, at times it is by fewer and less notable indications that we must be guided and, as these vary in intensity but never in importance, let us regard them somewhat in detail.

It may be accepted as a fairly safe rule that the acuter the initial symptoms the greater is the gravity of the case, and this will be emphasised—so far as experience carries me—if a rigor occurs accompanying or *immediately* preceding the acute abdominal pain. Each time I have met with its occurrence it has been associated with the gangrenous form of the disease, and I therefore regard it as of great prognostic and, indeed, diagnostic, value. The pain which attends the ultra acute form of appendicitis is, as a rule, of great severity but it may begin remote from the region in which it has its origin and in this way may lead to error. I have known it, from its early situation in the sacral region, mistaken for dysmenorrhœa, and its appearance in the left iliac region as due to a perimetritis. After a time, however, it is generally referred to the right iliac region, where, as a rule, it is attended by muscular rigidity which may be persistent or it may somewhat quickly pass away The pronounced character of this local muscular rigidity and the dulness on percussion which it is capable of giving rise to lead at times to the belief that the case is one of stercoral typhlitis, and the treatment may be disastrous. As a result of the morbid process within the abdominal walls they become more or less quickly involved in the rigidity and we find developed the hard flat, board like abdomen—an indication of such grave significance. But this valuable sign is not always present. There may be a perforated appendix or cæcum, or it may be an acutely gangrenous process at work, and the abdominal walls may be soft and yielding to the touch—unmarked by much tenderness and playing their part more or less freely in the act of respiration. To watch them regarding this last point is of importance, for from time to time it will be noted that a soft and slightly tender abdominal wall does not move in respiration, and that if a full inspiration be attempted it will be cut short ere it reaches its height. After a time abdominal fulness characterises most cases and measurements taken above and below the umbilicus are better guides to its increase or its diminution than mere visual recollection, but for its proper estimation two matters require consideration—the giving or the not giving of opium and the open or locked state of the bowels. As the opium tends to produce distension the occurrence of a stool may lessen the girth by a couple of inches and this in the presence of severe peritonitis. With the value of the pulse as a guide all are familiar and if its features were constant they would be of higher value, but they vary and they must be read in close connexion with all the others, especially the temperature. A quick *small* pulse—for its character is of greater value than its rapidity—with a high, or worse still, with a low temperature should attract immediate attention and in closely watching its behaviour—its tendency to quicken or to become slower, to become feebler or to gain in force—we find the surest of helps but it must be borne in mind that a suppurative peritonitis may be in progress with a fairly good pulse and a normal temperature. Very high temperature in the beginning with a rapid small pulse and notable although it may be not very acute *local* conditions, portend a state demanding quick interference, and although in many such cases this may count for little as regards the result, still such sufferers may and do, recover and their one chance lies in an early laparotomy To watch and to record every few hours the pulse and temperature ratio is a *sine quâ non* in all cases of appendicitis for in some with a normal temperature a quickening pulse may tell the true story and a pulse of 120 should as a rule be regarded as a very ominous sign. I recall one case in which an hour after the perforation of the appendix had occurred the pulse and temperature were normal, at the end of 12 hours the one was more than 130 and the other was 102° F and laparotomy saved the patient's life, while in another of gastric ulcer the pulse when the case was first seen was under 90 in a short time was nearly 120 and here again prompt interference carried with it success.[1]

Vomiting, common in many acute cases, is not always present in the ultra acute, but when it exists, when it is severe and continuous, or when having appeared early it disappears for a time and then returns and if the vomited matter be porraceous, spinach like, in character its prognostic value must not be overlooked.

In thus dealing with leading indications we may have begun in a wrong way, for after all ere we hear the patient's story, ere we feel his pulse or enter upon the consideration of his general state, we have seen his face and his attitude, and we have learnt much. The face '*grippe* —the face pourtrayed by Laennec—with the furrowed forehead and the *drawing upwards* of the features at once strikes us, and in some cases with due consideration given to all else may really determine for *operative interference*. It is most marked in perforation cases where suffering is severe, but it is present in many septic states where pain is not so prominent a feature. A facial aspect such as that referred to with restlessness and marked vital prostration may indicate in the malady we are contemplating as it may in other states a gravity unnoted in any other way Diarrhœa, infrequent in acute cases may be present in the very severe ones having its probable origin in some infective condition of the intestinal mucous membrane and pointing to the existence of a toxæmia. In the proper examination of such sufferers respiratory action will not escape observation, and decided costal respiration especially in the case of male subjects, is an indication of much prognostic value.

To some it may seem odd that no mention is made of the presence of the tumour in the right iliac fossa which is as characteristic of the majority of cases of acute appendicitis as is the sausage-shaped lump in intussusception, but in the form of the disease with which we are more particularly concerned it is not present because it either has not had time to form or more probably owing to the existing vital condition, would never form at all. To me—and in this attitude I differ with deference from the opinion of many others—its presence would not of necessity indicate interference, for I cannot accept the dictum that it is always significant of the presence of suppuration. Many such lumps have I seen disappear, as a perimetric mass disappears, and this so completely that an operation being performed in the quiescent condition small trace of their previous existence was discovered, certainly there was no pus Given, then, in an acute case a combination of the conditions we have considered—or it may be a notable development of two or three of them—rigor intensely severe abdominal pain, vomiting a quick small pulse—or a slow feeble one—a temperature very much raised or very much depressed, a hard contracted tender abdomen with its point of maximum tenderness within the right iliac sphere or one marked by the same local conditions with spreading tenderness getting quickly full, short costal respiration, and a drawn face, then will safety surely lie in immediate operation And with such conditions in the young or in the old the greater is the urgency as it is also in the case of a pregnant woman

Before finishing the consideration of diagnosis and its bearing upon operative interference it behoves that something be said regarding that "period of repose' which may occur in the manifestation of acute appendicitis and which, if unregarded may lead to serious error I take it that this is not confined to cases of severe appendicitis, for it is common to all perforative lesions of the abdominal viscera and its *raison d'être* is difficult of explanation Gangrene of the appendix with destruction of its nerves will not always explain it, for I have known it appear after a rupture of the intestine and in the case of a burst bladder and it is more probably due to some toxic or paralysing influence exerted on the nervous apparatus of the peritoneum itself, at all events, we recognise it in the cessation for a time of the most marked and disquieting phenomena in a grave case and the medical man and patient may alike be deceived by it And yet so far as my own experience carries *me*, there has generally been found in *local* conditions that which was sufficient to guide one aright. Pain, vomiting rapidity of pulse (this least of all) rise in temperature and the general feeling of distress may everyone of them be subsiding, but the local presence of tenderness, of abdominal retraction, of rigidity,' or of fulness (and any of these may be slight)—will keep awake the sense of anxiety and lead to safe action.[8] The absence of peristalsis as ascertained by the use of the stethoscope may prove of high value, and the estimation by a frequent blood count of increase in leucocytosis, especially as regards the polymorphonuclear cells, may be of great assistance. Unhappily in the case of fulminating appendicitis when a sufferer is too feeble to react to the toxæmia this last test may fail us, but in these cases we are not so much dependent upon it as in certain others where the question of suppuration becomes pre eminent.

---

[1] A case in which with high temperature there is a slow pulse is by some held as little likely to demand the help of the surgeon, but this is not always so for a year or two ago I had under my care a female patient whose pulse never rose much over 80 with a temperature of 102° to 104° F and in whom pus was evacuated with success on the fourth day of her illness.

Mr W H. Battle has in a valuable paper in THE LANCET[9] drawn attention to the great value attaching to the presence of effusion in the peritoneum as significant of early peritonitis, and where by percussion—or better, by flicking with the finger in the region of the flanks—dulness or thrill can be elicited, operation should be once performed Unfortunately, in a very considerable proportion of the most acute cases it is impossible to demonstrate the presence of any effusion and when the peritoneum is opened the state of dryness of the field of operation is very notable.

Rectal touch is of the highest value in the examination of cases of peritoneal inflammation and in appendicitis it should never be neglected It may confirm the diagnosis where the inflamed organ lies in the pelvis, it may demonstrate an acutely tender mass high up in the iliac fossa, it will certainly show an inflamed peritoneum when external abdominal tenderness may be slightly marked, and it may lead to the recognition of certain conditions that will alter entirely our original belief regarding the case.

Striking as are the phenomena that indicate a lethal appendicitis, it is still possible to misread them, and as the best way to avoid mistakes is to be aware of the possibilities of the errors we are likely to make, here are some that are feasible

Colic of the appendix—a condition the existence of which is denied by one of our best and ablest authorities—may, when severe, prevent the signs that usually attend a perforation or a rapidly destructive lesion, as witness the following story A Frenchman, aged 30 years, who never previously had had any abdominal trouble, was while dressing in the morning conscious of some uneasiness in the lower abdomen on the right side. Jokingly he told his wife that he had an "*appendicite,*" but as the crampy feeling quickly passed away so did his thought concerning it An hour after his midday meal, while walking in the street, he was seized with such intense abdominal pain that he became rapidly collapsed. Seen by his French physician the gravity of his case and its probable cause were at once recognised and in the afternoon, three or four hours after his seizure, I had the opportunity of examining him. He was suffering greatly, as evidenced by his complaints, by the pale, clammy state of his skin, by his anxious, drawn face, by his quick, feeble pulse, and by the intense rigidity of the muscles over the right iliac fossa. The diagnosis of a ruptured appendix seemed fairly clear, but as it was possible that a severe intestinal colic might explain his condition a full dose of morphia was given him. Means were taken to rally him from his state of shock and it was arranged that I should see him a few hours later On an evening visit—six hours from the time of his primary attack—he was found still collapsed, but his medical attendant, who had remained with him, stated that the morphia quieted him, that he had comparative ease, and that his general state had correspondingly improved A short time before my arrival the intense pain had returned, to be quickly succeeded by great vital depression So notable was this and so enduring that one of the two other physicians summoned by the family was opposed to operation not because he did not think it necessary but because he believed that the patient could not survive it. When the abdomen was opened and the appendix was found this was quite normal in appearance, as were the parts in its neighbourhood Its proximal third was, however, harder thicker and firmer than the rest of the organ but it bore on its surface no evidence of any notable lesion Search was then made for harm elsewhere, but as nothing was found to upset the diagnosis the appendix was removed. On further examination when the hardness and tenseness were much less evident it was discovered that a grain of barley still incased in its hard outer husk was lying transversely to the axis of the appendix with its sharp and pointed extremity buried in the submucous and muscular tissue and stretching—without perforation—the peritoneal covering of the organ.

In the absence of all naked-eye evidence of inflammation or ulceration externally or internally and in the passing *state of rigidity in the area of the appendix corresponding* to the position of the foreign body, I regard this as a true case of appendicular colic and although the pointed character of the barleycorn may have been able to inflict more irritation than a pointless body would, it is difficult to believe that by its presence any foreign body might not give rise to corresponding although less pronounced phenomena[10]

Renal and hepatic colic have proved sources of error in the recognition of acute appendicitis and I remember one case in which the mass formed round an inflamed appendix was in such close relationship with the liver that it was no matter for surprise that in the opening days of the illness the patient's sufferings were thought to be due to the passage of a gall stone

Under the conditions which mark some intestinal obstructions may be hidden the morbid changes associated with an ultra acute appendicitis, for the peritonitis thus provoked may, by its effects upon the neighbouring coils of intestine, give rise to such clinical phenomena as are inseparable from those of mechanical obstruction and yet with care it is possible to differentiate between them. Here is an instance in point. A young German woman in the best of health, who had suffered no abdominal symptoms of any kind, was in the early hours one morning seized with a severe pain in the abdomen accompanied by vomiting The French physician under whose care she was asked me to see her with him in the forenoon of the second day of her illness, when her state was as follows She had a temperature of 101° F, a fairly good pulse of 90, a flushed face, a rather full but in no wise tender abdomen unmarked by muscular rigidity but in which one observer thought coiling was visible, and constant, forcible vomiting She was constipated and there was little passage of flatus It appeared to me that such complaint of pain as could be elicited by examination was greatest in the right iliac region, but to abdominal pressure she was strangely tolerant. On the evening of the same day she was admitted to the British Hospital under my care, when it was found that her condition was worse, for her abdomen was fuller and the vomiting was quite stercoraceous in character, but she still had a raised temperature of 102° and the impression remained with me, largely on that account, that the obstruction was inflammatory—probably perityphlitic—and not mechanical in its nature In deference to the strongly expressed opinion of her own capable medical attendant, with whom the diagnosis of intestinal strangulation abode, a median section was performed and the intestine in the right iliac fossa was found to be much distended with its walls highly injected and as one neared the cæcum spots of lymph became visible upon its surface. Then there appeared what at first sight was taken for a loop of intestine—for it was nearly as large—a hugely dilated and distended appendix with plum coloured walls upon which at several points gangrenous areas were present When this was removed—and at its proximal end the dilatation was much less—it was found to contain three stercoliths, each of the size of a large olive, and so resembling those berries in colour and form as to be easily mistaken for that fruit The congested intestinal surfaces and the area in which the appendix lay were mopped with a strong mercurial solution a large drain was placed in the pouch of Douglas, and the wound was closed Despite the occurrence of a stitch abscess and the necessity for breaking up more or less the abdominal wound the patient made a good recovery for all the indications of obstruction disappeared with the operation and she quickly regained her health.

Among the many cases of severe appendicitis I have met with this is the only one in which the symptoms of intestinal obstruction were an early marked feature, and its story makes me question whether some of the fatal cases of obstruction which one encountered in earlier years were not due to a peritonitis of appendicular origin and the true cause of the fatality passed unrecognised.[11] In the absence of rise of temperature or other indication of inflammatory ill an error such as this is easily committed.

[8] For clear full, and valuable teaching on this point see a lecture by Mr Charters J Symonds delivered before the Hunterian Society in 1899; and a paper in THE LANCET of May 10th 1902, p 1305 by Mr A. E. Tubby on the Quiescent or Latent Period in the Course of Grave Abdominal Inflammations

[9] THE LANCET June 16th 1902, p 1679

[10] That the personal element in this case had much to do with its apparent gravity was after the operation suspected and since then the medical attendant of the patient has told me that while he was suffering from a nephritic colic his condition was very similar to but much less acute than that which led to the removal of his appendix

The close anatomical relationship of the appendix with the right adnexa of the uterus leads occasionally to errors in diagnosis, for an acute inflammatory lesion starting in the area of the right iliac fossa may possibly owe its origin to a suppurating tube and not to an appendicitis. As a rule, however, the onset in the former is not so severe (the pain may be most acute in the *left* side) and examination by the rectum or vagina will in a very large majority of cases lead to a recognition of the true state of affairs. But simulation may arise in another way, as witness the following case. A young English woman, aged 20 years, was admitted into the British Hospital with a diagnosis of acute appendicitis The story of her medical attendant was that he had seen her on the previous evening, when he had found her with a history of sudden and severe abdominal pain having its origin in the right iliac fossa, with a tender and rigid lower abdomen, with a quick pulse, and with a temperature of 102° F On the following morning this condition had not much changed, she had passed a restless night. She still complained of much abdominal suffering and was still feverish, the temperature being 101° and the pulse 110 The abdomen was full its muscular walls were rigid, it was tender over the whole of the lower third, but especially tender on the right side and in the middle line Rectal examination revealed the pouch of Douglas distended and boggy, evidently with effused blood. Inquiry then elicited the fact that having barely ceased menstruating she had taken a cold bath, immediately subsequently to which the acute pain made its appearance. As she was a virgin and there was nothing in her case to suggest the possible existence of an ectopic gestation it was believed that some distended ovarian or Fallopian vein had given way under the vascular strain produced by the cold bath, and that her symptoms of peritonism owed their origin to the intra peritoneal hæmorrhage. She was treated accordingly and with steady diminution in the effusion she was quickly restored to well being

Pelvic peritonitis associated with gonorrhœa in the female I have seen simulate very closely appendicular inflammation, for it had its most acute manifestation on the right side, but here again rectal, followed by vaginal, examination and the recognition of the state of the right fornix made the case clear And in young men a peritonitis of similar origin should not be forgotten, for although it is rare to find it unassociated with an epididymitis or the presence of a gonorrhœal discharge, it may occur independently of them and by the condition of the vesiculæ seminales as ascertained by rectal examination will the diagnosis be made sure. The intense pain in the inguino-scrotal and iliac region, the severe and repeated vomiting the high fever, the rigid lower abdomen, the facies, and the general condition fill in the picture of appendicitis

With our attention so strongly directed to the appendix as the probable source of all evil in the region of the abdomen in which it is situated we are apt to forget that in the cæcum itself there may arise pathological conditions the acute vital manifestations of which may be indistinguishable from those arising within or around its attached neighbour Here is a case in point A woman in middle life, with a strongly marked history of gout, consulted me regarding some abdominal pain from which she had suffered for a good many months. It was spasmodic in character, sometimes occurred at night did not return very often, and was closely associated, in her thinking with the taking of animal food. She suffered much from constipation but there had been no vomiting On examining her there was nothing in the abdomen to attract especial attention except that in the region of the cæcum the percussion note seemed to be duller than usual, and when firm pressure was made here and slight tenderness elicited there rose under the hand a soft cylindrical mass which quickly disappeared. While this was tangible she was conscious of the presence of the pain which formed her great complaint. That this was a thickened cæcum thrown into contraction by pressure, on its surface was evident and I made very careful search for any evidence of growth or obstruction in the colon, but with a negative result. When obtained her motions were natural, she had never passed blood or mucus at stool and was not subject to diarrhœa. A few days afterwards I was hurriedly sent for as she had been seized with sudden severe pain in the right iliac fossa and she then presented the conditions which usually characterise an acute perityphlitis She had, however, a good and not too rapid pulse and her temperature was 101° F There had been no vomiting, there was no marked fulness of the abdomen, but it was tender over the right lower area, and there was in that situation notable muscular rigidity With my previous knowledge of her I believed that some ulcerative process connected with the diseased cæcum was the most likely cause of her acute suffering In the evening she was easier, the pain and the local evidences of it were less marked, the pulse, a little over 100, was of good force, the temperature was 102°, and the abdomen, albeit fuller by one inch and with marked rigidity in the cæcal region, was absolutely soft elsewhere and rose easily and freely on deep inspiration The succeeding night was a restless one and in the morning the general condition evidenced no improvement, for the pulse was still over 100 and of diminished strength. The temperature was 103°, the face was drawn and anxious, and although the abdominal measurement showed a diminution of a full inch and its walls were still pliant there was increase in tenderness both as regards its area and its intensity The bowels had moved freely and spontaneously and the motion was in all respects a characteristically healthy one. Believing that a peritonitis was in progress—a diagnosis in which Sir Henry Blanc, who saw the case with me, agreed—I with his able assistance, opened the abdomen. The escape of a considerable quantity of intensely bloody serum and the appearance of congested intestine confirmed our belief, and in drawing up the cæcum, the walls of which were greatly thickened, two gangrenous patches were visible on its surface. One, of the diameter of a shilling, was situated on its inner and lateral aspect, and the other, measuring at least five times the size of the other, presented on its anterior surface. The smaller one was treated by invagination and the other by a free opening and the insertion of a Paul's tube. The dilated cavity of the cæcum was quite empty and its mucous lining generally seemed to be healthy The ascending and transverse colon was carefully examined, but there was no change to be detected in it either as regards its dimensions or the thickness of its walls By interrupted sutures the cæcum was attached to the peritoneum and the wound was closed. The patient made an excellent recovery and her after history was of interest, for she developed within a few months of the operation a malignant stricture of the splenic flexure of the colon, which has since been removed with success That this occurred apart from the morbid state of the cæcum I feel well assured, for what the first operation revealed was a true cæcitis or typhlitis in which similar pathological changes occurred to those which we meet with in a chronic appendicitis Its chief interest to me lies in the fact that had I not seen the patient upon a previous occasion and formed some idea of the existing conditions there was nothing in the picture of her grave illness to distinguish it from that of an ultra acute appendicitis.

Of the close simulation of lethal appendicitis by perforated gastric or duodenal ulcer, especially the latter, and by the twisting of the pedicle of an ovarian cyst, I have no personal experience, but I know from the records of others how strong the counterfeit may be, and it is always well to remember the fact when preparing to operate upon a seemingly severe case of appendicitis. Little reference is made in text-books to the fact that it is at times difficult to differentiate between appendicitis and typhoid fever and yet the problem is a notable one If operation always and of necessity followed the diagnosis of appendicitis I am sure that certain cases of enteric fever would be submitted to unnecessary and dangerous interference, for I have seen the zymotic disease ushered in with very acute perityphlitic symptoms, with severe pain, with abdominal tenderness and right-sided feeling of distress may everyone of them be subsiding, but the local presence of tenderness, of abdominal retraction, of rigidity, or of fulness (and any of these may be slight)—will keep awake the sense of anxiety and lead to safe action.[8] The absence of peristalsis as ascertained by the use of the stethoscope may prove of high value, and the estimation by a frequent blood count of increase in leucocytosis, especially as regards the polymorphonuclear cells, may be of great assistance. Unhappily in the case of fulminating appendicitis when a sufferer is too feeble to react to the toxæmia this last test may fail us, but in these cases we are not so much dependent upon it as in certain others where the question of suppuration becomes pre eminent.

---

[11] This reflection is strengthened when one calls to mind—as most operating surgeons can call to mind—cases in which in desperate conditions of obstruction all that could be done was an enterectomy and this with the happiest results It is true that the relief of intestinal distension and pressure may at times serve to release a strangulation or permit the withdrawal of an intussusception but it is quite as likely that at others the immediate good which opening the intestine produces represents the removal of the urgent obstructive symptoms that inflammation in the appendix may and can produce.

Mr W H. Battle has in a valuable paper in THE LANCET[9] drawn attention to the great value attaching to the presence of effusion in the peritoneum as significant of early peritonitis, and where by percussion—or better, by flicking with the finger in the region of the flanks—dulness or thrill can be elicited, operation should be once performed. Unfortunately, in a very considerable proportion of the most acute cases it is impossible to demonstrate the presence of any effusion and when the peritoneum is opened the state of dryness of the field of operation is very notable.

Rectal touch is of the highest value in the examination of cases of peritoneal inflammation and in appendicitis it should never be neglected. It may confirm the diagnosis where the inflamed organ lies in the pelvis, it may demonstrate an acutely tender mass high up in the iliac fossa, it will certainly show an inflamed peritoneum when external abdominal tenderness may be slightly marked, and it may lead to the recognition of certain conditions that will alter entirely our original belief regarding the case.

Striking as are the phenomena that indicate a lethal appendicitis, it is still possible to misread them, and as the best way to avoid mistakes is to be aware of the possibilities of the errors we are likely to make, here are some that are feasible.

Colic of the appendix—a condition the existence of which is denied by one of our best and ablest authorities—may, when severe, prevent the signs that usually attend a perforation or a rapidly destructive lesion, as witness the following story. A Frenchman, aged 30 years, who never previously had had any abdominal trouble, was while dressing in the morning conscious of some uneasiness in the lower abdomen on the right side. Jokingly he told his wife that he had an "*appendicite*," but as the crampy feeling quickly passed away so did his thought concerning it. An hour after his midday meal, while walking in the street, he was seized with such intense abdominal pain that he became rapidly collapsed. Seen by his French physician the gravity of his case and its probable cause were at once recognised and in the afternoon, three or four hours after his seizure, I had the opportunity of examining him. He was suffering greatly, as evidenced by his complaints, by the pale, clammy state of his skin, by his anxious, drawn face, by his quick, feeble pulse, and by the intense rigidity of the muscles over the right iliac fossa. The diagnosis of a ruptured appendix seemed fairly clear, but as it was possible that a severe intestinal colic might explain his condition a full dose of morphia was given him. Means were taken to rally him from his state of shock and it was arranged that I should see him a few hours later. On an evening visit—six hours from the time of his primary attack—he was found still collapsed, but his medical attendant who had remained with him, stated that the morphia quieted him, that he had comparative ease, and that his general state had correspondingly improved. A short time before my arrival the intense pain had returned, to be quickly succeeded by great vital depression. So notable was this and so enduring that one of the two other physicians summoned by the family was opposed to operation not because he did not think it necessary but because he believed that the patient could not survive it. When the abdomen was opened and the appendix was found this was quite normal in appearance, as were the parts in its neighbourhood. Its proximal third was, however, harder, thicker and firmer than the rest of the organ but it bore on its surface no evidence of any notable lesion. Search was then made for harm elsewhere, but as nothing was found to upset the diagnosis the appendix was removed. On further examination when the hardness and tenseness were much less evident it was discovered that a grain of barley still incased in its hard outer husk was lying transversely to the axis of the appendix with its sharp and pointed extremity buried in the submucous and muscular tissue and stretching—without perforation—the peritoneal covering of the organ.

In the absence of all naked eye evidence of inflammation or ulceration externally or internally and in the passing state of rigidity in the area of the appendix corresponding to the position of the foreign body, I regard this as a true case of appendicular colic and although the pointed character of the barleycorn may have been able to inflict more irritation than a pointless body would, it is difficult to believe that by its presence any foreign body might not give rise to corresponding although less pronounced phenomena.[10]

Renal and hepatic colic have proved sources of error in the recognition of acute appendicitis and I remember one case in which the mass formed round an inflamed appendix was in such close relationship with the liver that it was no matter for surprise that in the opening days of the illness the patient's sufferings were thought to be due to the passage of a gall stone.

Under the conditions which mark some intestinal obstructions may be hidden the morbid changes associated with an ultra acute appendicitis, for the peritonitis thus provoked may, by its effects upon the neighbouring coils of intestine, give rise to such clinical phenomena as are inseparable from those of mechanical obstruction and yet with care it is possible to differentiate between them. Here is an instance in point. A young German woman in the best of health, who had suffered no abdominal symptoms of any kind, was in the early hours one morning seized with a severe pain in the abdomen accompanied by vomiting. The French physician under whose care she was asked me to see her with him in the forenoon of the second day of her illness, when her state was as follows. She had a temperature of 101° F., a fairly good pulse of 90, a flushed face, a rather full but in no wise tender abdomen unmarked by muscular rigidity but in which one observer thought coiling was visible, and constant, forcible vomiting. She was constipated and there was little passage of flatus. It appeared to me that such complaint of pain as could be elicited by examination was greatest in the right iliac region, but to abdominal pressure she was strangely tolerant. On the evening of the same day she was admitted to the British Hospital under my care when it was found that her condition was worse, for her abdomen was fuller and the vomiting was quite stercoraceous in character, but she still had a raised temperature of 102° and the impression remained with me, largely on that account, that the obstruction was inflammatory—probably perityphlitic—and not mechanical in its nature. In deference to the strongly expressed opinion of her own capable medical attendant, with whom the diagnosis of intestinal strangulation abode, a median section was performed and the intestine in the right iliac fossa was found to be much distended with its walls highly injected and as one neared the cæcum spots of lymph became visible upon its surface. Then there appeared what at first sight was taken for a loop of intestine—for it was nearly as large—a hugely dilated and distended appendix with plum coloured walls upon which at several points gangrenous areas were present. When this was removed—and at its proximal end the dilatation was much less—it was found to contain three stercoliths, each of the size of a large olive, and so resembling those berries in colour and form as to be easily mistaken for that fruit. The congested intestinal surfaces and the area in which the appendix lay were mopped with a strong mercurial solution a large drain was placed in the pouch of Douglas, and the wound was closed. Despite the occurrence of a stitch abscess and the necessity for breaking up more or less the abdominal wound, the patient made a good recovery, for all the indications of obstruction disappeared with the operation and she quickly regained her health.

Among the many cases of severe appendicitis I have met she began to amend, and ultimately recovered from such a condition as one had learned by sad experience to regard as quite a hopeless one Several times in 24 hours she received a subcutaneous injection of some ounces of normal saline fluid to which were added small doses of strychnine—for her heart s action was of the feeblest—and in and through these means she exists to-day

[10] That the personal element in this case had much to do with its apparent gravity was after the operation suspected and since then the medical attendant of the patient has told me that while he was suffering from a nephritic colic his condition was very similar to but much less acute than that which led to the removal of his appendix.

Here, then, may end my quest. Early operation in appendicitis (that is, within the first 48 hours) I practise only in the grave cases and I am happily able to bear strong testimony to its value and its success, for I have never found it increase a peritonitis already in existence—indeed, it has cured it. The difficulty has often been the prompt recognition of those conditions in which delay too often spells deaths, and my endeavour has been to render, if possible, their recognition more facile and less hesitating

THE HISTORY OF THE DISCOVERY OF TRYPANOSOMES IN MAN

BY RUBERT W BOYCE, M.B LOND, F.R.S.,
HOLT PROFESSOR OF PATHOLOGY IN UNIVERSITY COLLEGE, LIVERPOOL

RONALD ROSS C B., F R C S. ENG, F R.S.,
MAJOR, I.M.S (RETIRED) PROFESSOR OF TROPICAL MEDICINE IN UNIVERSITY COLLEGE, LIVERPOOL

AND

CHARLES S SHERRINGTON, M.A., M.D CANTAB., F R.S.,
HOLT PROFESSOR OF PHYSIOLOGY IN UNIVERSITY COLLEGE, LIVERPOOL.

MISTAKES as to priority in scientific discoveries are so frequently made, are so easily perpetuated and are so discouraging to workers that we shall present no apology for attempting a critical history of the discovery of trypanosomes as parasites in man. There is the more call for someone to undertake this task because the discovery promises to be an important one and because some fragmentary discussion regarding it has already taken place So far as we know at present there are five possible claimants in the field—namely Hehir, Barron, Nepveu, Forde, and Dutton. We propose to examine their respective claims as thoroughly as possible, but must premise that we can judge of these claims only by means of the published documents which are now before us and which we mention specifically in the footnote references

Major Patrick Hehir I.M.S. (1891, 1892)—So far as we know no claim has yet been advanced in favour of this observer being the discoverer of the human trypanosome, but as this claim may be made in the future and as his case appears to be as good as those of the two following observers, we may as well deal with it here. The first mention made by Major Hehir of anything like a trypanosome is contained in his work on Malaria (1891) p. 14[1] where he states that he met with "trichomonas like bodies in six out of his 343 cases and 'pyriform" bodies in 39 cases. Of the first form he says "It remains transparent and structureless throughout, but acquires two or more filamentary processes after leaving the corpuscles. Originally I thought that these were distinct structures and in no way related to the other forms" (i.e., Laveran s bodies) 'It may be found in the blood cells or free. In the latter case it soon acquires two flagellae (*sic*), one at each extremity, and sometimes throws out small flagellae from its irregular border. This last clause suggests the undulatory membrane of trypanosomes and monads. Of the pyriform body he says that it possesses 'a single active flagella' and that 'it varies considerably in size, it is structureless, and remains so except that after some time mobile pigment granules are seen in it. After a few hours from this period it is set free, it appears to be a misshapen crescent." In thinking that his flagellate bodies issue from the red corpuscles, Major Hehir evidently had the hæmogregarines in mind but he seems to have dropped this idea in his next publication. The presence of pigment in the pyriform body suggests that it was a malarial gametocyte. The work is illustrated with rough drawings in outline, and those of the trichomonas like and pyriform bodies (Plate IV, Figs. 3 and 4) may just possibly be meant for trypanosomes. Next year (1892) Major Hehir published a long paper on parasites found in the blood and excreta in cases of cholera,'[2] and on page 3 mentions finding trichomonas-like bodies with a wavy border on one side and long tapering flagellæ arising from the extremities." This description might certainly suggest monads as much as trypanosomes, but, on the other hand, some of the drawings of these objects (Plate V, Fig 3) are distinctly like the latter, especially the one with a vacuole at one end and a flagellum at the other which certainly seems to be meant to be a trypanosome. With regard to the nomenclature used by Major Hehir for his flagellate organisms (*Trichomonas*), we may remark that there was at one time considerable confusion between the parasite groups of trypanosomes and monads[3] Both groups have undulatory fringes, or at least lateral flagella, and the number of terminal flagella in the monad group was by no means quickly determined. Lewis[4] at first thought that his trypanosome of rats belonged to the monad group and various names have been given to trypanosomes by various observers, as for instance, *Hæmatomonas* (Mitrophanow) *Herpetomonas* (Saville Kent), and *Trichomonas* (Crookshank, 1890) The last is the name used by Major Hehir in 1891 and 1892. Gruby's name *Trypanosoma* did not come into general use until later, and we cannot therefore object to Major Hehir that he did not use it in his papers under reference Apart from this it may be argued that he must have been observing trypanosomes whatever his nomenclature was, because organisms of the monad group (e.g., *Cercomonas* Davaine or *Trichomonas* Donné) have not yet been demonstrated with certainty in the blood

We certainly cannot say definitely that Major Hehir did not find trypanosomes in human blood, but, on the other hand we should be sorry to admit definitely, on the published evidence, that he did find them. His first paper referred to above[5] describes and figures many objects which he considers to be parasites of malaria but which are more like artifacts and at all events are not admitted by any of the best authorities on malaria. In his paper on the organisms of cholera he gives 15 full page plates of rough drawings of very singular objects which appear to be zoologically impossible. In 1895 Hankin[6] expressed an opinion that most of Major Hehir s cholera parasites were "nothing but crystals of common salt various kinds of precipitates, fragments of fibrin, altered red or white blood corpuscles, or even masses of bacteria. Next year Major Hehir[7] published another long paper on malaria in which he claims to have found the spores of the malaria parasites in soil and water, to have detected 'free flagella" in syphilitic blood, and to have proved that "the Amœba coli is a true flagellated sporozoon.' We would add, however, that at one time Major Hehir was considered an authority[8] and his paper on cholera was issued as a special supplement of the *Indian Medical Gazette* Numerous other papers by him of a nature similar to those we have quoted can be found in the pages of that journal from 1891 up to his reply to Hankin.[9] Since 1897 however, we have seen no further contributions from his pen.

Dr Alexander Barron (1894)—Dr Laveran seems to have been the first to draw attention by a brief note in his book "Traité du Paludisme" to a short communication made to the Liverpool Medical Institution by Dr Barron,[10] then professor of pathology at University College, Liverpool. We transcribe the entire passage as we find it. 'December 6th, 1894.—Dr Barron related a case of a lady, aged 39, the muscular rigidity, with indeed all the phenomena, except the tumour formation, that mark appendicular inflammation, and within a week the appearance of typhoid spots reveals the true nature of the malady In such cases our sheet anchor in diagnosis will rest with the increase or the diminution of the leucocytes, for in the case of the fever they will diminish, while in the other, especially if pus-formation occur, they will enormously increase.

A condition difficult of explanation yet not of recognition, and apt to occur in connexion with many abdominal troubles, may, when appearing with the appendix as its exciting cause, lead us astray in regard to prognosis and to treatment. I refer to peritonism We all know it, but I am sure we do not all know—too often cannot know—how to estimate it aright. It is so extraordinarily like peritonitis that it is hard, sometimes impossible, to distinguish between them, and yet the importance and the gravity of the one are occasionally only mimicked by the other Its bearing upon the matter under consideration is, however, important Sir Frederick Treves has drawn attention to the fact that many cases of appendicitis occurring in women begin during the course of menstruation and "that this is explained by the circumstance that the two organs concerned are closely allied and that they certainly can mutually disturb one another" With this important observation it is well to bear in mind this other—one more or less familiar to many practitioners and to which Dr S J Gee has particularly drawn attention—that at times in women a day or two preceding the flow they have abdominal pain, they shiver, they vomit, and they get a full—at times a very tender—abdomen, they have a quick pulse and a rise in temperature, they lie in bed with their limbs drawn up and they present a typical picture of peritonitis Yet when the discharge appears the whole picture is changed, every grave sign and symptom disappear, and the woman is well She has had an attack of peritonism, and if this were misread and on exploration of the pelvis there was found no evidence of harm there, an unnecessary laparotomy might be performed in the search of a ruptured appendix. Even when the appendix is the cause of a peritonism it may be difficult to recognise the offender for through the abdominal distension which is one of the most notable features of the latter condition, by the gastric intolerance and the constipation attendant upon it which also mark its presence we are met with the phenomena of a pseudo-occlusion. The swollen abdomen lacks, however, the tenderness of the truly inflamed one, and even when there are a certain quickness of pulse and a certain rise in temperature the freedom with which the patient moves and breathes and the expression of the face suggest the presence of a deception. I have a note of a case in which, in the third attack of a recurrent appendicitis, the abdomen was so distended and the vomiting so persistent that immediate operation was contemplated, but close and constant observation demonstrated the facts that the temperature never rose over 99 4° F and that the pulse, excellent in quality, never much exceeded 100 The expression, too was in no wise drawn, and such abdominal tenderness as existed was only discovered in the right iliac fossa The condition of absolute constipation was pronounced, but copious and repeated enemata brought down gas mixed with a small quantity of fæcal matter and this gradually augmented, so that by the end of the second day a satisfactory movement was obtained The meteorism gradually subsided and there could be felt in the region of the appendix a thick, rather tender, cord. On the removal of this—for it was an enlarged appendix—a few weeks later there was in its neighbourhood no evidence of any recent peritonitis.[12]

Important as the condition of peritonism always is, and at times most grave in its import, it is difficult to accept unreservedly the dictum of some that by its very presence it calls for immediate operation, for, as we have seen, it does not always mean great things, and it may pass away leaving no gross evidence in its train. But it is not within the peritoneal cavity alone that conditions may arise which render the recognition of a perityphlitis a difficulty A commencing basal pleurisy or pneumonia, involving as they are apt to do the pleural surface of the diaphragm may tend to a train of symptoms that, without sufficient care in their investigation, may easily be mistaken for those arising from an acute peritoneal inflammation. This fact has been long the common knowledge of most practitioners and it has led many to investigate as a matter of routine the pulmonary conditions in all acute disease. By following this rule the error is not likely to be made, for the auscultatory sounds associated with a pleural lesion are, as a rule very widely different from those one finds in association with an inflamed peritoneum, but as Mr. H. L. Barnard[13] has lately pointed out in a most interesting paper there are certain conditions which may tend to mislead and have, indeed, misled some excellent and careful surgeons. Apart from the help visual examination of the chest and the use of the stethoscope will surely bring, the consideration of the temperature—especially at the beginning of the illness—of the pulse and respiration rate, of the catching character of the latter, of the fact that however hard and rigid the abdomen may feel it will momentarily relax in the act of inspiration, and that its tenderness is chiefly "superficial and firm deep pressure with the hand may be permitted," will direct us aright and turn the thoughts to the true direction in which the patient is suffering

With reference to treatment I have not much to add I hold with many that the giving of opium is apt to mask guiding symptoms and that it is best if possible to avoid it. But if it must be given—and at times acute suffering imperatively demands it—opium by suppository or laudanum given as an injection, is better than morphia subcutaneously If movement of the bowels be called for—and it very often is—then we must depend upon the stimulating action of an enema, aperients given by the mouth are fraught with danger The method of operation in those cases done early—that is, within the first 48 hours—is, as a rule, straightforward and simple, and I would only add that I have found its simplicity, and I believe its safety, increased by the incision being made closer to the anterior superior spine of the ilium than is usually advised. It is quite possible to display and to remove the appendix without any protrusion of the small intestine. What this may mean to a somewhat inexperienced operator a recollection of the past with many of us will best explain, and inasmuch as these operations fall under the category of emergencies and must, if they are to be of any service, often be undertaken by the practitioner in attendance upon the case, the easier the task is for him the better will it be for his patient. In the cleaning and drainage of the inflammatory area and its surroundings I have, as a rule, a greater belief in the use of marine sponges and "swabs" than in irrigation, and in large-sized drainage-tubes with gauze wicks than in gauze packing The removal of the gauze is often a very painful process for the sufferer and it is not always so efficient as we may believe it to be; for every now and then a wound thus treated will look well on its surface, while in its depths there is confined an exudation which should have been drained away And in certain circumstances, in a somewhat prolonged retention of the drainage-tubes, I have found only good—the process of granulation has expelled them and the tracks through which they passed have quickly closed and have shown no tendency to yielding in after days. In the after management of bad cases—cases in which, despite early operation and all therein involved the septic process is not checked and the evidences of peritoneal infection do not subside—I would bear testimony to the extreme value of normal saline solution used subcutaneously I am not likely to forget one case under the care of Dr Lalou and myself in the Asile Evangélique of Cannes, the happy management of which rested almost entirely in his hands It was that of a young woman upon whom I operated within 24 hours of her seizure, in the presence of a well established dry peritonitis having its origin in a gangrenous appendix. In this patient, although improvement followed for a time, yet, despite free drainage and the means that best meet such conditions, on the fifth day of her illness her state seemed desperate. Her aspect was that of a dying woman, her abdomen, drum-like in form, was intensely tender over all its surface, her temperature was high (103° F), and her pulse was quick-running—well nigh uncountable, and she had that incessant gulping vomiting of dark matter so characteristic in the closing scenes of a septic peritonitis Yet she lives, for so soon as her bowels moved and a free diuresis was established—and for this the saline infusion was responsible—

[12] Lejars: Chirurgie d Urgence p 415

[13] THE LANCET August 2nd 1902, p 280

He begins by setting forth that the researches described by him were made in Algeria in the summer of 1888 and in August, 1890 (the latter apparently being the researches during which, as he claims in his article of 1898 he discovered the human trypanosome) He then passes in review all the parasitic forms which he has observed in the blood of malaria patients, but insists only on the points which he believes to be new (recalling a similar statement by Major Hehir) These parasitic forms are certainly as novel as they are numerous. They consist of "*algues inférieures et schizomycètes*" and of "*infusoires flagellés et sporozoaires*" By the flagellate infusoria he means (p 48) Laveran's parasites which were then often thought to be of this nature. Of the former class he discovers "*masses zoogléiques* ' floating in great numbers in the blood of almost all the pernicious cases and disappearing on recovery, a microbacillus, a '*bactérien en biscuit* ' which occurs not only in the blood of cases of malaria but in their stools and in the water of pits reputed to be malarious, "*bactériens en flotteurs* ', also an "*algue véritable*" which demonstrates its existence in the blood by developing in (apparently) sealed specimens, also *spirilla* which are generally fixed to the red corpuscles—"they therefore recall the bodies described by Laveran under the name of spherical bodies with flagella" (*sic*), also a "*streptocoque paludique*", also a "*bactérie careniforme* ' which is furnished at its two extremities with long lashes perpendicular to its axis and which suddenly transforms itself into a crescent, also a "*bactérie érucante*" which he says has a "vague resemblance to the caterpillar of our gardens" and which has "singularly perplexed" the author because it may either be "a distinct species or a phase of the coccidium paludicum (*sic*) or a schizomycete." A similar body was found in the portal vein.

In connexion with the '*infusoires flagellés* ' the author describes what he thinks are Laveran's parasites He begins with the spores, of which he has been able to count 20 in a single cell of a "villosité intestinale." They remain quiet for a time, to the number of four five, or six, attached to a single corpuscle, but later give evidence of their existence by producing "formidable accidents." He refers especially to those of the larger hæmamœbæ which take the form of a starfish One finds this free in serum, 'animated with movements so rapid that it was very difficult to seize its form in an exact manner" There are other "*amiboïdes bien curieux* ' which have four branches but which appear to lose the fourth foot when seen in profile (*sic*). He also describes some very singular "*corps vésiculeux* ' We note especially the "*corps claviforme* ' and the "*corps en gourde* ' Three of the latter were found fixed on the same corpuscle and had the appearance of gorged leeches or even of *Cysticercus cellulosæ* The author also describes finding in the milk of two nurses an organism with the form of a retort All these forms including certain "*vésicules à queue*" and '*vésicules en larmes bataviques* ' are, according to the author, "*très probablement des formes de transition très voisines de celles du trypanosome* On p 50 he says that he is convinced that they ' *rapprochent beaucoup de certaines grégarines, de certaines coccides*," but that he is unable to determine exactly their phases and much less their species Nevertheless, he thinks that they represent "*le stade sphérique ou la période de segmentation du trypanosome*" Why so he does not explain. The figures of these bodies (Figs. 3, 12, and 23) resemble nothing that we know of in connexion with trypanosomes or indeed, with anything else. It is unnecessary to deal with his descriptions of Laveran's crescents and his so-called "flagellate bodies" except to note that the latter are "almost always fixed inside the red corpuscles ' which is of course seldom, if ever the case. He describes three kinds of crescents. Fig 31 is like these bodies but Fig 16 distinctly represents fragments of red corpuscles He finds free flagella very frequently (as Major Hehir does). Some of his *corps flagellés* are triangular with a flagellum at each angle (Figs 17 and 18) One of these (Fig 17) is the only one of the drawings which presents the smallest likeness to a trypanosome, but on reference to the text (p 48 paragraphs 4 9 and 10) it appears to be one of Laveran's flagellate bodies of the triangular pattern.

Lest it be pretended that Dr Nepveu has here drawn a real trypanosome we may remark that Fig 17 represents a long narrow body with two flagella, with knobs at their ends, issuing from one extremity and (?) a third flagellum at the other extremity Now the adult trypanosome is certainly long and narrow but has only one flagellum, while the fission forms certainly may have two or more flagella, but are broad and generally partially divided objects with the flagella issuing from the sides—quite different, in fact, from the figure. But the matter is finally decided by the presence of the little knobs at the end of the flagella in the illustration. Dr Nepveu had evidently read of the enlargement often seen at the end of Laveran's so-called flagellum, and consequently gives such an enlargement to all his figures of flagellate bodies (Figs. 17 and 18) and refers to it in his text as *une petite vésicule terminale* Now the flagellum of the trypanosome never possesses an enlargement of this kind. Hence he was clearly not drawing a trypanosome. His other flagellate bodies strongly remind us of some of Major Hehir's drawings and are probably blood plates with filaments of fibrin attached It is impossible to know what he means by his *corps vermiformes.* One would suspect filariæ but for the illustration, which suggests nothing of the kind. The illustrations of this work consist of a page of drawings in outline roughly scratched by the point of a pen They are very similar to those of Major Hehir, and most of them probably represent exactly the same objects—namely, artifacts, blood plates, fibrin, vacuoles, and adventitious bodies.

As we have already mentioned, he says near the end of his work "Je n'ai jamais pu trouver, malgré le plus grand soin, la trypanomonade ou le trypanosome de Danilewski, mais certainement des caractères assez nombreux semblent en indiquer cependant la présence, ou tout au moins la présence d'un hématozoaire très voisin" This passage speaks for itself. It has been suggested that by "*le trypanosome de Danilewski*" Dr Nepveu meant a particular species of trypanosome which he could not find, but this reading is impossible because Danilewski mentioned many kinds of trypanosomes found in many animals Nepveu evidently meant that he could not find trypanomonads or trypanosomes such as Danilewski had described. (We may explain that the name *Trypanomonas* was at one time given by Danilewski to Lewis's trypanosome of the rat in order to distinguish it from the trypanosome of frogs. He thought that the former is an immature form of the latter,[15] or at least a young trypanosome, and Dr Nepveu seems to have some confused remembrance of this erroneous hypothesis We have already spoken of Labbé's use of the word *Trypanomonas*) Reviewing this paper of Dr Nepveu we see that he expressly denies in it having ever found trypanosomes in his researches of 1888 and 1890 He claims only to have found "characters which indicate the presence ' of trypanosomes, but he gives no evidence whatever that the objects he refers to have any connexion with trypanosomes, or, indeed, with any other parasite In fact, the whole paper suggests that with the exception perhaps of Laveran's crescents, he was not describing true parasitic organisms at all, but simply a series of artifacts

A little later in the same *Comptes Rendus*, Dr Nepveu[16] records the discovery of yet another couple of parasites—namely, of flagellate bodies included in the leucocytes in cases of malarial fever and of certain polygonal organisms in the same. The illustrations of the former are unlike anything which would now be considered possible, and the discovery has not been confirmed It is interesting to note however that two of the cases in which these organisms occurred (p 700) have the same names as two of the cases (Genestet and Cabane) in which the author claimed seven years later to have found trypanosomes[17] They suffered also from the same disease, pernicious fever The polygonal cells have not been studied except by the author

After this year (1891) we find a series of short publications by the author in the *Comptes Rendus de la Société de Biologie* We cannot refer to them here, but would advise the reader who is interested in this matter to look through them The heading of most of them suggests that Dr Nepveu was at Marseilles during this period.

We have thus given a brief review of such of Dr Nepveu's writings as we are acquainted with, and we would advise the reader to study them for himself if he wishes to form an independent opinion regarding them. We would suggest, however, that he study them in conjunction with the writings of Major Hehir and a paper on artifacts in the blood written by one of us (Ross[18]) subject of a uterine fibroid, which had ceased to bleed after phlebitis and an attack of influenza who, in the early part of this year, there being no hæmorrhage of any kind, began to become anæmic and had a peculiar earthy complexion, suggesting possible malignant disease. On examination in August no evidence of any organic disease beyond the fibroid could be found, but the blood contained large numbers of flagellated protozoa, as many as eight or ten in the field of the microscope $\frac{1}{12}$ oil immersion. She was not seen again until October, when she appeared to be, and said she was, perfectly well. No protozoa could be found She was treated with arsenic, aloes, and iron. No change in diet or surroundings." The note ends here and the minutes of the Liverpool Medical Institution give no additional details On Jan. 16th, 1902, one of us formally asked the members of the institution whether any of them could throw further light on the subject The only reply given was one by Professor H Briggs, who stated that the case was his own and that "Dr Barron's organism was in his own opinion, not like Dr Dutton's specimens" (We may explain that the phrase 'Dr Dutton's specimens" refers to some preparations of the human trypanosomes found by him and Mr R M Forde in the Gambia some weeks previously, as will be presently described.) A short abstract of these proceedings will be found in the *British Medical Journal* [11] Dr Barron's case is the more tantalising because, being an expert pathologist, he was not likely to have been misled by artifacts It will be noted, however, that the parasites were said to be flagellated protozoa, that they were very numerous, that there are no statements regarding their size, form, structure, and zoological affinities, and no drawings of them, and that it is not mentioned whether the patient had ever been in the tropics. Professor Briggs's statement suggests that they were not trypanosomes, and in fact it remains impossible to ascertain what they were

[18] Ross A List of Natural Appearances in the Blood which have been Mistaken for Forms of the Malaria Parasite, Indian Medical Gazette, 1894 p. 441

Dr Gustav Nepveu (1898)—So far as we know this is the first observer who actually uses the name "trypanosome" for the flagellate organisms which he claims to have found in human blood. His paper [12] has no illustrations and is only a page and a quarter in length, but the author states perfectly definitely in it that he had found trypanosomes in human blood. He begins by remarking that up to the present trypanosomes had been found only in certain animals, but he refers to Dr Barron's case He proceeds

> In 1890 in pursuance of *(à la suite de)* researches made in Algeria on the parasite of malaria I found in the blood of a patient in whom Laverania also were present conjointly with them a flagellate organism which was common enough I counted about three of them in each preparation of 18 mm square About this time (see Nepveu: Etude sur les Parasites du Sang chez les Paludiques 21 1891 Bulletins et Memoires de la Société de Biologie) I already gave some of the drawings which I had collected up to that time I always hoped to be able to complete by a more detailed study these *first observations but since then I have found the parasite again only* on rare occasions I therefore decided to give the few details which follow in the hope of drawing the attention of naturalists and physicians who will be able to complete these researches
>
> This trypanosome shows all the characters of the genus: general form a colourless homogeneous membrane of which one of the borders thinner and more hyaline than the other is animated by the characteristic undulatory movements This membrane carries a nucleus and a fine flagellum placed in front the undulations of which follow each other rapidly
>
> It is thus that it appeared in Khill (quotidian fever) and in Cabane *(pernicious comatose fever)* In a third patient, *Genestet I observed* organisms which I thought were related to those described under the name of trypanomones" a form which is perhaps only a stage of evolution of trypanosomes In this patient the organisms were furnished with two flagella at one of their extremities Labbé [13] has described a trypanomone of this kind
>
> In more than 200 patients for the most part malarial of which I have studied the blood I have found these various forms only in six Three of these were suffering from quotidian fever (Khill Langevelde Bichiolli) one from a tertian type of fever (Hendrick) two from pernicious comatose fever (Cabane Genestet) The seventh observation was made on *Dr X——*, who was apparently in good health (larval paludism)
>
> In none of these patients have I observed any symptoms corresponding to this special parasite invasion They were almost all invaded by the Laverania which dominate in all and always under diverse forms This seems to be therefore a pure and simple coincidence which I think worthy of notice
>
> In conclusion the trypanosome ought to be placed among the parasites of the blood of man I cannot give with all the precision desirable a more complete description of this variety I therefore do not wish to give it a particular name It would be better to begin with to establish the similarities and differences which I find between this parasite of man and the congeneric ones observed in animals and to complete first our morphological and evolutive study *of it*

This is all. At a cursory glance nothing could be more convincing than this paper, but those who have studied the discoveries of new parasites which are so frequently made (e.g., in epilepsy, goitre, cholera, syphilis, small pox, &c.) will perhaps wish to inquire further In the first place, we note that Dr Nepveu's description of his trypanosome is merely what may be called a generic description and not a specific one, that is, it would apply equally well to almost all the kinds of trypanosomes known Anyone who has seen the familiar trypanosomes of animals, or has even read an account of them in the text-books, could have written such a description He gives no measurements and no drawings, he does not inform us (a thing which he might easily have done) which of the many trypanosomes figured in the text-books, and differing in many particulars from each other, most resemble his, and the position of the nucleus, the staining reactions, and the details of movement are not noted (In the original passage, "*Un noyau et un flagelle mince placé en avant*," the word *placé*, being singular, refers only to *flagelle*) He does not (in spite of his concluding sentence) make any effort to differentiate his trypanosomes from those of animals The excuse which he gives for this lack of detail—namely, that he has found the parasite only on rare occasions—is scarcely adequate. Since then the most exact drawings and descriptions have been given from a single case, and yet Dr Nepveu was not able to give them with the material of six (if not seven) cases. Surely he might have retained some preparations from some of these cases from which photographs or drawings at least could have been made. The reader should note that he expressly denies that his parasites were pathogenetic. This does not accord with what has been found in connexion with the majority of cases recently reported.

It will be observed that in one place he states that in the case of Genestet he had found organisms furnished with two flagella *at one of their extremities*, that these organisms appeared to be allied to those called trypanomonads, 'a form which is perhaps only a stage of evolution of the trypanosome," and that "Labbé has described a trypanomone of this kind." It has been gravely contended in favour of Dr Nepveu's claim that the trypanosome with two flagella is so characteristic an object that it is not likely to have been imagined by him It is true that trypanosomes undergoing fission have two or more flagella, but as will be seen on reference to the classical works of Rabinowitsch and Kempner, Laveran and Mesnil, Bradford and Plimmer, these flagella are unfortunately *seldom or never at one end* In fact, each derivative organism has its own flagellum, and the freshly formed flagella are seen at the sides of the parent organism Dr Nepveu's remark seems to weaken rather than to support his case, and suggests that he had found, or thought that he had found, some multiflagellate organism such as a monad. Still more unfortunate is his reference to Labbé. On looking at the work of Labbé mentioned we find that his organism certainly had two flagella, but that they are placed *one at each end* And Labbé does not apply the name "trypanomones" only to this kind but to the whole genus, much less does he give the name to organisms with two flagella at one end, as Dr Nepveu suggests. The idea that trypanomonads are an earlier stage of trypanosomes is based upon a confusion of Danilewski's which we shall mention again.

Near the beginning of his paper Dr Nepveu says that his discovery was originally made "*en 1890, à la suite de recherches faites en Algérie*," and that about this time he had already published drawings in the publications of the Société de Biologie On referring to this article of his [14] we find no drawing which purports to be, or which even clearly denotes, a trypanosome, while the article concludes with the most definite statement that he had not found trypanosomes at all, "in spite of the greatest care." The only justification which appears to exist for his reference to this earlier paper of his is that he claimed in it to have found "numerous characters seeming to indicate the presence of them (the trypanosomes) or, at least, of hæmatozoa like them" (p 50)—a very different matter By a close study of this and of a succeeding paper of Dr Nepveu we find, in fact, that he has discovered many other parasites besides trypanosomes. This paper of 1891 is headed "Par M le Professeur G Nepveu de Marseille."

[14] Nepveu: Étude sur les Parasites du Sang chez les Paludiques, Comptes Rendus et Memoires de la Société de Biologie, 1891 p 39

We may, perhaps, be justified in concluding this discussion by some words of Charles Darwin.[25] "I feel sure," he writes to a correspondent, "as long as species mongers have their vanity tickled by seeing their own names appended to a species, because they miserably described it in two or three lines, we shall have the same vast amount of bad work as at present and which is enough to dishearten any man who is willing to work out any branch with care and time." In order to obtain the credit for an observation much more is necessary than just to record once in print that it has been made, without taking any trouble to convince others, without publishing accurate descriptions or drawings, or even without giving a full account of the circumstances under which the observation was made. Of course, science cannot accept this sort of thing, to do so would be to admit every kind of pretender For instance, anyone can record a statement to the effect that he has seen a new parasite, and can even *furnish* a *good* general description of it drawn from descriptions of allied parasites found in other hosts and given in the text-books That such a thing is done with intent to deceive is happily not very likely, but unfortunately it can often be done unconsciously by inexperienced students (especially in connexion with minute parasites of the blood), who having found some object which seems to them to accord with the text-book description, rush into print, full of ardour for their new discovery A timely remembrance of the words of Darwin would not only save many such from the disappointment of finding their claims rejected, but would also guard the interests of "the man who is willing to work out any branch with care and time."

ON THE PERMANENT CARE OF THE FEEBLE-MINDED[1]

BY MRS ELLEN F PINSENT,

CHAIRMAN OF THE AFTER-CARE COMMITTEE OF THE BIRMINGHAM SCHOOL BOARD

I HAVE some hesitation in speaking of the value of the work of an after-care committee when the only one of which I know anything has been in existence so short a time, but I may succeed in giving some idea of the difficulties with which it is necessary to contend The first important question is as to the advisability of establishing such committees. On this point I have no hesitation I am most anxious to see them established wherever there are classes for the mentally deficient. I think that all those who have had anything to do with these children are agreed that there is no stated age when they can be considered grown up or treated as responsible adults Many, I believe most, are as much children at 16 years of age as they were at 10, the only difference being that, as at 16 they are capable of doing greater harm, they therefore require greater care when they reach that more dangerous age. I do not think it possible that much lasting help can be given by members of after-care committees in the majority of cases, and yet the children in these very cases are just those who are absolutely unfit to face the world without permanent care.

When we started an after-care committee in Birmingham our immediate aim was to find situations for those children who left the special classes capable of work, and also to see if there was anything that could be done for the hopeless cases where the children were found to be incapable of work. This, I say, was the immediate object but it was by no means the most important in the minds of those who formed the committee It was established first and foremost as an investigation committee with the object of estimating the worth of the laborious and expensive education given in special classes. It was hoped that if for some years after they left school the careers of these unfortunate children were closely watched and accurately reported the committee would then have some facts to place before educationalists which would enable them to judge how far the special class really meets the requirements of mentally deficient children. We hope, too, to be able to show how many of those who leave special classes ultimately become self supporting or even partially self supporting It is too early in our history to place any great confidence in our figures, but such as they are I will give them to you

We had 48 children on our list to begin with and of these we found it impossible to trace 13 This, I hope, is a larger percentage than will ever occur again. Many of these children had left school for some years before we began work. Now that each case is taken up at once and constantly watched we shall have a better chance of tracing them, though I am afraid we shall always lose a certain number The parents are perpetually flitting, and as there are so few after care committees, when a child goes to another town we have no organisation to whom to hand him or her over We feel this a good deal in Birmingham, for, although our children may only go a short distance—to Smethwick, Aston, Handsworth, or Yardley, which are all in reality part of one great population—yet these children are often completely lost, as none of these places have even special classes, much less after care committees. Thus, some years' work in a special class may be rendered almost useless from the fact that the child's parents have moved out of our school board district

Before passing on I should like to point out that the children who are perpetually wandering are almost always the offspring of low and degraded parents and probably if they were found would swell the numbers of the incapable and hopeless. This should not be forgotten when conclusions are drawn from our statistics. It also points to the advisability of such children being placed in a boarding school where they could be kept under permanent control and not left to the chance of their parents remaining in the neighbourhood of a special class or of an after-care committee. There can be no doubt that many parents of feeble-minded children, belonging as they so often do to the street-hawker and irregularly employed class, are even more migratory than the rest of town populations. This is one of our most disheartening difficulties, for, unless the after-care association can establish permanent custodial homes it must always lose a large percentage of cases, and every lost case may mean, and generally does mean, a future generation of feeble-minded children.

Of the 35 remaining persons 16 are at work The average age of these 16 persons is 17 years, and the average weekly wage which they earn is 5s 9*d*.—one boy earns 10s. a week. We have not at present been established long enough to know how often these persons change their situations, or the amount of time wasted during such changes, which if considerable would, of course, lower their weekly wage. But, speaking generally, I believe that our investigations will show that they are perpetually changing their situations. Certainly of the four cases which have come under my own eye only one is satisfactory, one person is too bad to work at all, one never keeps his situation more than a few weeks and the other never more than a few months. Neither of the latter will ever be capable of self support after their near relations die and I think it probable that both will find their way into gaol. Here they will cost at least as much as in an industrial colony where I feel sure that working under supervision both could have contributed largely to their own support. These cases I believe to be typical of most of the 16. A small percentage will get along passably, but by far the greater number will eventually be found in the prison, the penitentiary, or the workhouse. The next seven children on our list, although capable of work, are out of work. This you will notice is nearly one third of the total number of cases in which the subjects are capable of work. Our after-care committee will probably get them work of some kind, but by that time others will have lost their situations and I fancy our books will show that this is about the usual proportion. Our utmost efforts will probably prove inadequate, there will always remain a third doing nothing If those who fail to keep their situations were placed in industrial colonies they would work continously with greater profit both to themselves and to society at large.

I have now accounted for 23 out of our 35 children. Of the remaining 12 one has died, five are so bad that they should be placed at once in some asylum or home, and six are being looked after fairly well at home but are incapable of work and will have to be provided for on the death of the mother I have said fairly well looked after and by this I mean that they are clothed, fed, and kept passably clean but I do not believe for a minute that they are protected from all chance of moral harm Some of them are girls who should never be

---

[25] F Darwin: Charles Darwin p. 159 London: John Murray 1902.

[1] A paper read before a Conference held at Leicester on Nov 26th 1902, upon the Treatment of the Mentally Defective.

Of course, as with Major Hehir and Dr Barron, we cannot definitely say that Dr Nepveu did not find trypanosomes in human blood. Although his paper of 1891 contradicts his statement of 1898, that he discovered them in 1890, yet it is possible that he saw them later We have no means of judging The paper of 1898 is so vaguely worded that it is impossible to ascertain from it when and where the observations were made—that is, if they were not all made in Algeria in or before 1890 Beyond this the cases are neither localised nor dated Are we to suppose that all the cases were found in Algeria in 1890 or that some were found subsequently up to 1898? In the latter event, where were they found? Did Dr Nepveu return to Algeria after 1890 or did he find the cases in Marseilles or elsewhere? Surely he ought to have given some exact information on these points Surely, also, considering the large amount of material he possessed in his six or seven cases, and in view of the importance of the discovery which he claims, he ought not to have allowed seven years to elapse before publishing, he ought to have given much more precise details than he did give and he ought to have placed his discovery beyond cavil by demonstrating his organisms to persons capable of judging them. If he did so, where are the facts recorded?

At the same time his various papers fail to convince us that the author possessed any really accurate knowledge even of the literature of trypanosomes, or indeed of malaria Like the papers of Major Hehir, they suggest, that the author was an enthusiastic but inexperienced observer who mistook everything seen under a strong lens for some kind of parasite. If we cannot assure ourselves that these observers did not find flagellate organisms in the blood we certainly cannot, in spite of their statements, feel convinced that they did. It is possible that their flagellate organisms were artifacts, such as many of their other organisms certainly seem to be. There is no good evidence that Major Hehir ever saw his trichomonas like body and there is no more evidence that Dr Nepveu ever saw his trypanosome than that he saw flagellate bodies within the leucocytes or numerous curiosities which he mentions as existing in malarial blood. Even if the reader decides to grant these observers the benefit of the doubt he will be forced to consider the difficult question as to which of the two deserves the priority Certainly Hehir's drawing of 1892 (Plate V, Fig 3) presents as good an idea of a trypanosome as Dr Nepveu's very general description of 1898, and was published six years earlier For our own part, unless some fresh evidence can be produced in their favour, we shall be forced to conclude that the claims of Major Hehir, Dr Barron, and Dr Nepveu are all of them, to say the least, very questionable. Laveran and Mesnil have already independently come to the same conclusion regarding those of Dr Barron and Dr Nepveu. Referring to their papers of 1894 and 1898 they say, "Jusque dans ces derniers temps on n avait cité que des cas très douteux de trypanosomes chez l'homme."[19] We have consulted with Dr Laveran on the subject, and he authorises us to say that he sees no reason for changing this opinion of the papers of Dr Barron and Dr Nepveu

Mr R M. Forde and Dr J S Dutton (1901) —This case need not detain us long The first publication was by Dr J S Dutton [20] He states that the case in which the parasites were found was admitted into hospital at Bathurst, Gambia, with fever on May 10th, 1901 under the care of the colonial surgeon, Mr R M Forde The patient's blood was examined by Mr Forde, and Dr Dutton says "Mr Forde informed me that he saw very many actively moving worm like bodies whose nature he was unable to ascertain." The patient was now invalided to England and on August 12th entered the Royal Southern Hospital, Liverpool, where he suffered from "three short periods of pyrexia" and other symptoms. Here Dr Dutton examined his blood for malarial parasites on two occasions with negative results and Dr C J Macalister recorded his case In December the patient arrived in the Gambia again and Mr Forde asked Dr Dutton (who also had arrived in the Gambia on a scientific mission) to examine his blood once more. Dr Dutton expressly admits (p 455) that this request was made "on account of" Mr Forde s previous observation of the "actively moving worm like bodies whose nature he (Mr Forde) was unable to ascertain.' On doing so (Dec 15th) Dr Dutton, who had previously found nothing in the patient's blood now succeeded in detecting unquestionable trypanosomes to the number of only three in three slides.

Such is the history of the discovery as taken from this paper The rest of the paper gives a close analysis of the symptoms of the case as observed by Mr Forde, Dr Macalister, and Dr Dutton, and a detailed description of the parasites, including their form, movement, numbers, size, and staining reactions, as observed by Dr Dutton during a long study of the subject. He gives also a coloured drawing of the stained parasite and photographs of it and of allied organisms in animals (*T Lewisi*, *Brucei*, and *equiperdum*), and compares the human parasite, which he names "*T gambiense*," with these, and also the symptoms produced by it in man with those produced by them in animals The previous claim of Dr Nepveu is briefly considered. Charts comparing the temperature in man and in nagana are added In a footnote at the conclusion of the paper Dr Dutton states that "since going to press" he has found the same parasites in one out of 115 dried blood films taken from native children in the Gambia during his visit there

We should add that shortly after the discovery was made both Dr Dutton and the patient returned to England. Here Dr Dutton, Dr H E Annett, and Mr J L Todd continued the study of the case, both of the parasites and of the symptoms. The parasites were exhibited at the Royal Society, and at Liverpool in connexion with the annual meeting of the British Medical Association, and both the case and the parasites were shown to many others, including ourselves. Dr Dutton contributed another paper on the subject to the British Medical Association, July 29th, 1902.[21] This is practically a repetition of the former paper, except that the consideration of Dr Nepveu's claim is omitted

Meantime Mr Forde, who had first seen the parasites in May, 1901, seems to have published nothing on the subject. On Sept. 1st, 1902, however, a paper from his pen[22] appeared giving some of the clinical details of the case during the periods when the patient was under his care in 1901 He substantiates Dr Dutton's account of the discovery, but adds that when he (Mr Forde) first saw the parasites he "prematurely pronounced" them to be "a species of filaria", that this conclusion "became doubtful after repeated observations of the parasite", that he showed the case to Dr Dutton, and that Dr Dutton "at once recognised" "the parasite" "as a species of trypanosoma." Mr Forde adds that it was also Dr Dutton who recognised the peculiar undulant nature of the fever

The leading facts appear to be clear and undisputed. Later, however, Mr Forde[23] published a letter in which he seems to claim having made the discovery by himself in May, 1901, when he first saw the parasites. This view may be contested, as we have his own words to the effect that he then thought the parasites were a species of filaria and that it was Dr Dutton who recognised them to be a *species of* trypanosoma. We may note, also, that he published nothing on the subject (so far as we know) until 15 months after his first observation, and three months after Dr Dutton's first publication On the other hand, it was undoubtedly Mr Forde who drew Dr Dutton's attention to the existence of parasites in the case In the circumstances we think that most people will consent to the opinion that the names of Mr Forde and Dr Dutton ought to be associated in the history of the discovery Dr Macalister also contributed some clinical details. Whatever the claims of others may be it was certainly Dr Dutton who first established the existence of trypanosomes in human beings in a manner fully satisfactory to science, and it was also he who was the first to give adequate descriptions and illustrations of the new parasite and a comparison of the symptoms with those of other forms of trypanosomatosis in animals. The case of Mr Forde and Dr Dutton has been so thoroughly investigated, especially by the latter, and is so well attested, that it is unnecessary to examine the confirmations of the discovery which have already been made public—namely, a case of Dr Habershon Dr Manson and Mr Daniels, and some fresh cases of Dr Dutton and Dr Todd [4] is not possible to secure at day schools, (*d*) mentally defective children living so far from any special day school that it would be impossible for them to attend, and (*e*) certain defective children known as "moral defectives." 3. Epileptics 4 Epileptics who are also feeble-minded 5. Feeble-minded children who are also crippled, blind, or deaf-mute 6. Imbeciles and idiots.

Class B —Those over school age, including the following sub-divisions (1) mentally deficient but capable of industrial work under supervision—i.e., cases for a permanent industrial colony, (2) mentally deficient and incapable of work—i.e, cases for a permanent colony, (3) epileptics who are capable of work in a colony (4) feeble minded epileptics, (5) feeble-minded persons who are also crippled, blind, or deaf mutes, and (6) imbeciles and idiots.

The ultimate aim of this inquiry is, of course, to collect evidence showing the necessity for boarding schools to be supplemented by permanent industrial colonies or permanent custodial homes to which children who were unfit to face life on their own responsibility could be transferred from such boarding schools In this way they would never be allowed the liberty which they can only misuse to their own degradation and to the degradation of the society in which they live Theoretically it may be hard to decide what degree of mental deficiency renders people morally irresponsible for their actions, but when it comes to the practical side, the question as to which cases will ever become independent of help and self supporting, it is not nearly so hard a matter Let us face the worst that might happen. Let us grant that a very small percentage of the feeble-minded would be kept in a colony who might have gone through life without serious harm to themselves or to others and then let us weigh this evil—for I grant it would be an evil—against the infinite amount of suffering and moral degradation caused by the fact that people of defective intellect are allowed the full liberty of responsible citizens, that they are allowed to make the lives of their own families miserable and to leave behind them others as defective as themselves Ultimately such people do have some restriction or other put upon their personal liberty, too often in gaol, too often in penitentiaries, and most often, perhaps, in the workhouse. We are only asking for restriction a few years sooner and we offer instead of the usual story of crime, shame, and pauperism that these years should be spent happily and safely and filled with pleasant and honest labour

As to the exact plan of action which our committee will think it wise to adopt I cannot speak. The difficulties ahead make one almost despair Would it be better to try to win the local authorities first or to appeal direct to the Government? Is it primarily a matter for the guardians or for the city councils? Might we not have better hopes of success if both those authorities combined and went together to the Local Government Board? Among all the suggestions for the treatment of this evil there is only one on which I have a really clear opinion and this is not very helpful as it is merely negative. I should like, if possible, to avoid any appeal to private charity Any consideration of the numbers we have to deal with must convince us that private charity would be entirely unable to cope with them This is an affair which touches the welfare of the nation and only the nation can deal adequately with it Asylums and homes supported by private charity are only a mitigation and can never provide for all As long as we refuse to deal with the whole question feeble-mindedness will go on increasing It is probable that private charity postpones the day when the State will see the necessity of stepping in. Private charity has been at work for many years and the evil is still increasing On the other hand, there can be little doubt that a thorough and complete system of State intervention would lead to a steady decrease in the numbers of the mentally deficient.

Harborne Birmingham

WATER SUPPLY OF TEIGNMOUTH.—At the meeting of the Teignmouth district council held on Feb 3rd Dr F C. H. Piggott, the medical officer of health, presented a report on the water supply of the town He stated that the water from the Coombe brook (which is supplied to about half the inhabitants of Teignmouth) after analysis by the Clinical Research Association was declared to be 'unfit for drinking '

ANEURYSM OF THE ASCENDING ARCH OF THE AORTA IN A SMALL BOY

A POST-MORTEM SURPRISE

BY ALFRED C JORDAN, M D CANTAB

A BOY, aged six and a half years, was brought to consult me on Sept. 8th, 1902, for headache and vomiting, and he had a discharge from both ears These symptoms had begun two days previously Unlike his brothers and sisters, he had always been a delicate child. The ears began to discharge for the first time before he was two years old after whooping cough He was a pale, ill nourished boy with the rough skin which is characteristic of malnutrition He complained of headache, chiefly felt above the right ear There was no tenderness over the mastoid process or above the ear There was some muco-purulent discharge from both ears His temperature was 101° F On the 9th the headache was worse, the vomiting continued and the temperature was 102° On the 10th the vomiting had almost ceased but the temperature was 103° On the 13th the following note was made. The temperature was 99 4°, the headache was less severe, there were no vomiting, no fits, or twitching, the bowels were constipated, the pulse was regular, not slow The pupils were small, equal, and reacted well to light and to accommodation, consensual light reflex was normal, there was no squint The heart and lungs were normal. The abdomen was full, it was not tense or tender, there was no enlargement of the liver or spleen. The boy was pale. On the 14th the left knee began to swell and to be painful, there was effusion into the joint. There was no sore-throat and the temperature was normal The headache was slight and the boy seemed better in other respects. The specific gravity of the urine was 1015, acid and clear, there was no albumin or sugar On the 16th Dr Howard Tooth saw the boy with me. The optic discs and the fundi were normal. He was given ten grain doses of sodium salicylate three times a day on the supposition that the swelling of the knee was of the nature of acute rheumatism. On the 20th the temperature remained normal. The effusion into the left knee joint, which had continued up to the 18th had now begun to subside The joint was far less painful and tender than on the 16th. On the 23rd he was free from headache and his temperature remained normal. The knee was painless though the effusion had not yet entirely cleared up There was still some discharge from the ears He was sitting up playing with his toys He continued to improve during the next three days The knee became normal On the 26th he was up playing and laughing, when suddenly he turned pale and died.

To summarise the chief points of the case a boy, aged six and a half years, who had been the subject of *otitis media* since babyhood, began to suffer with headache, vomiting, and fever on Sept 6th These symptoms grew worse until the 10th, then they began to subside, and on the 20th they left him. On the 14th the left knee began to swell. Effusion into the joint increased up to the 18th and then began to diminish, the knee being normal at the time of his death. On the 26th when he was apparently convalescent, he suddenly died.

Necropsy —At the post-mortem examination the brain and meninges were quite normal in all respects. The tympanic cavities contained muco-purulent fluid, the right containing more than the left. In the left lateral sinus there was an ante mortem clot, white and tough, loosely adherent The lining of the sinus was smooth and healthy In the abdomen everything was normal On removing the sternum the pericardium was seen to be distended, on incising it a quantity of blood stained serum escaped and the heart was found to be enveloped in a thick coat of dark blood clot. On removing this the cause of the boy s sudden death was at once evident, for on the ascending arch of the aorta, on its anterior surface, was a sacculated, light-red swelling, in the centre of which was a horizontal slit-like opening (Fig 1) On the corresponding point of the inner surface of the aorta was a triangular opening with sharp edges (Fig 2) The triangular flap, attached along the shortest side of the triangle, was pushed outward into the lumen of the sac. Evidently a small opening in the intima had first allowed out of the house by themselves, instead of which I know that they are prone to wander alone for hours in the streets A poor mother with other children cannot give her whole time and strength to the weak minded member of the family The child must take her chance during the busy hours of the day These girls are often of a clinging and affectionate disposition and will follow any man who chooses to speak kindly to them We who pay the rates and taxes will have to support these girls in the end. Would it not be wiser to do so at once, instead of waiting until they have produced others for us and our children to support? Once more it is for permanent industrial and custodial homes which we must work and the chief duty of an after care committee is to collect the evidence which will demonstrate their necessity No after care committee, however vigilant its members, can watch over the feeble minded at all hours of the day and keep them from harm, but what an after care committee *can* do is to show the public the result of its investigations and go on publishing facts until ratepayers, Poor law guardians, and city councillors are convinced.

I am very anxious to take this opportunity of approaching the Poor-law guardians on the subject of the worst cases with which after care committees will have to deal. I do this not at all in a spirit of captious criticism—for I recognise fully the enormous difficulties with which the administrators of the Poor law have to deal—but I am really anxious to come to a better understanding The Poor law should, I think, be a help to us, but at present it is only a difficulty It seems to me that we are pulling in exactly opposite directions and until we pull together I despair of any good results. It appears to me that it is the policy of the Poor law authorities to keep cases of extreme mental deficiency and imbecility out of the workhouse as long as possible. Our policy is to do all we can to persuade parents to avail themselves of the workhouse as a refuge, generally the only possible one, for their uncontrollable children. I have failed to find any asylum or home within the means of poor parents and therefore when a case is pressing the Poor law is our only hope, and I find that when, generally with much difficulty, we have persuaded the parents to apply it is quite impossible to predict what will happen I will give you two puzzling cases.

CASE 1.—This is a girl about ten years old. Her father is living and she has a stepmother Her father earns from 30*s* to 35*s* a week and would be glad to pay something for her maintenance if she could be placed in some home. She is absolutely uncontrollable. I have seen her father obliged to hold her still by main force while she struggled and fought One day she put the cat on the fire, another she undressed herself in the street Her stepmother cannot take her out as she is uncontrollable, and therefore when the necessary shopping has to be done she is tied to the kitchen table and left to howl. The medical superintendent of the school board turned her out of a special class as an imbecile and as being incapable of benefiting by instruction therein The after care committee could find no home or asylum within the parents' means and therefore with some difficulty it persuaded the parents to apply to the guardians A medical man was sent by the Poor law authorities to examine the child I suppose he must have found her in a quiet mood, for he said that she was not imbecile and refused to sign the necessary certificate. After a good deal of further trouble on the part of the lady who undertook this case I understand it was suggested by the guardians that the child should be sent to one of their cottage homes Here she would be one of 19 normal children I can well imagine the life she would have led the unfortunate foster mother in charge of the cottage home However, luckily for her and the other children under her charge, the girl's father refuses to pay the 7*s* a week which the guardians asked and which he considers, justly I think, more than he can afford When she has half killed some neighbour's child we may succeed in getting her removed Burning the cat, unfortunately, was not enough. But is not the whole thing an extraordinary muddle? Medical officer No 1 says the child is an imbecile, while medical officer No 2 says she is not an imbecile The school board authorities say she is too bad even for a special class, while the Poor law authorities say that she is fit to mix with normal children

CASE 2.—This is a girl, about 16 years of age nearly blind, nearly deaf, and nearly dumb, very feeble minded and violent-tempered with the other children Her parents are unable to control her, she escapes from the house and wanders in the street, and she has locked the baby up in the cellar, but she also has never done anything to justify her forcible removal. A member of the after care committee after infinite trouble persuaded the parents to apply to the guardians. The medical man in this case, which to the lay mind is certainly not so pronounced as the other, signed the certificate and the child was taken to the city asylum. The committee breathed a sigh of relief—once more she was out of harm's way Presently the authorities settled that the parents should contribute 2*s* 6*d* a week. The father was proved to have earned an average wage of £2 7*s* 6*d* a week for the last two months No one could say that the contribution was too much, and, of course, he should have been glad to pay it, but he refused and the child was brought back to the frightful risks of her former life. We could not prevent it—we are powerless until the child is proved to be dangerous. The liberty of the subject must not be interfered with and the parent must have his way This is surely one of the points on which we need fresh legislation

Before passing on I should like to emphasise two things illustrated by these cases First, the extraordinary variety of medical opinion as to what constitutes an imbecile, and secondly the extraordinary variety of payments demanded by the Poor law authorities. From one man earning 35*s* a week they ask 7*s*, and from another earning £2 7*s* 6*d* they ask only 2*s* 6*d* It is a little perplexing to have to work with such variable quantities.

It is not surprising that the Poor law authorities wish to keep these children out of the workhouses, as they have no proper provision for them. They might, of course, send them away to idiot asylums where they could be properly graded and looked after, but this is extremely expensive Sometimes it is done, but the more usual plan is to place them in the epileptic ward of the infirmary where they are associated with all degrees of mental deficiency, from epileptics whose intellect is normal to raving idiots In this case one has most pity for the epileptics whose intellects are still normal though at the same time it is not ideal for feeble minded children I know of one boy on our after-care list who is said to be trainable to some extent and who is now in the infirmary of a workhouse spending his time in imitating the cries and gestures of two or three male idiots who are inmates of the same ward. If unions were to combine to have separate graded establishments for such cases there would be no difficulty in finding sufficient numbers to render the grading satisfactory But I am told that there is a difficulty about getting the Government grant of 3*s* a head, as many of these children could not be certified under the Lunacy Acts. Here, again, it would seem as if the only remedy lay in fresh legislation on the subject

Before concluding I should like to mention the last bit of work recently undertaken by the Birmingham After Care Committee. It has been known to us for some time that there were a large number of idiots, imbeciles, epileptics, and feeble-minded persons who had never passed through special classes and who were not on our original after care list We made it our business to collect, with the help of the school board officials and others, a list of these cases When we had obtained a sufficient number it was thought advisable to appoint a sub-committee consisting almost entirely of medical men who have most kindly undertaken to examine and to report on every case In this way we hope at no great interval to be in a position to inform the city council of the extent to which the evil exists. We shall, at any rate, know the facts, and, more than this, we shall have classified the cases under various heads, which should help us later if it is found possible to do anything for these dangerous and unfortunate members of society I will give you the heads under which we propose to classify our cases They fall naturally into two main divisions, those of school age and those over school age.

Class A—Those of school age (i.e., under 16 years) These again sub divide into 1 Those suitable for special classes for the feeble minded These, of course, have already been dealt with by the school board, although our committee of medical men is finding out some few cases which have hitherto escaped notice. 2. Cases which for various reasons could be better dealt with in boarding schools for the mentally deficient. Such cases have been recognised by the London School Board and classified under the following heads (*a*) mentally defective children who but for their defect would be committed to industrial or truant schools, (*b*) mentally defective children living in very bad homes, (*c*) mentally defective children whose regular attendance it alum, tannic acid, turpentine, perchloride of iron, and adrenalin chloride. The bleeding would sometimes stop for a quarter of an hour after the little cavity had been plugged, but would soon burst out afresh as vigorously as ever The best result was undoubtedly obtained from adrenalin chloride (1 in 1000 Parke, Davis and Co.), the bleeding being diminished during its employment but not arrested. On the evening of the 8th, when the boy had been bleeding almost continually for five days and nights and had become anæmic and restless, yawning and sighing at times, with a variable pulse sometimes irregular in character and at other times as rapid as 120 per minute, I asked Mr Bilton Pollard to meet me in consultation. On hearing of the various styptics already employed Mr Pollard suggested a trial of calcium chloride. A small pledget of wool was steeped in some of this solution (30 grains to an ounce) and then inserted into the little cavity This was shortly removed and replaced by another and yet again by several others, until the removed plug showed no blood stain whatever A final plug was, of course, left *in situ*. The cessation of bleeding was now complete. The nurse in attendance was then ordered to moisten the inserted plug with some fresh solution every 20 minutes. We left the house shortly after 8 P M and this treatment was continued for two hours when the boy fell asleep and did not wake till six o clock on the following morning there being no return whatever of the hæmorrhage. When I saw him in the morning the plug was gone, but there was not the slightest return of the bleeding I bade the nurse continue painting the gums for three days in case a fresh outbreak might manifest itself, but this, however fortunately, did not occur, no bleeding whatsoever taking place since the first employment of the calcium chloride.

The family to which the patient belonged was of pure Scotch descent and consisted of two boys and a girl. The little patient was the eldest, then came his brother aged five and a half years who also was afflicted with hæmophilia, and lastly a girl, aged four and a half years, who as might be expected, was free from the disease. On the mother s side—and it is, of course, through this branch of the family that we search for a history—there was evidence of the direct heredity of this pitiful complaint, one of her brothers having died from hæmorrhage, at the age of five years and four months, after extraction of a tooth Till then there was no suspicion that he was afflicted with this malady and it was a standing puzzle how it was that he always 'bruised' so easily and sometimes without any apparent cause. The first evidence of any kind in the present case that the parents had of their elder son s bleeding propensity was when he was at the age of six months He was circumcised at that time and the bleeding was only stopped after several days duration with some difficulty Directly he began to walk bruises began to appear before that time none having occurred. At the age of two and a half years he cut his tongue with a tin toy, and again when a little older he slightly severed the frænum of his upper lip with a piece of hard sharp toast, both of these slight injuries giving rise to hæmorrhage of a troublesome kind. As lately as six weeks previously to this present attack he had some obstinate hæmorrhage, lasting 11 days, in the course of shedding an upper central incisor tooth. This was partially arrested by removing the extremely loose tooth and touching the gum with the actual cautery There was slight oozing after this for some time which the mother said appeared to subside gradually of its own accord. His younger brother, like himself is nearly always covered with large and painful bruises. He was circumcised at the age of three months and when a little older injured the frænum of his tongue, both of these trivial wounds giving rise to annoying and somewhat obstinate bleeding

Summing up this case I would not have it thought that I consider calcium chloride to be an unknown or untried local styptic although, at the same time, from questions which I have put to several practitioners of undeniable experience, it appears to be far less generally appreciated in this use than as an internal remedy But when it succeeds and perchloride of iron and adrenalin chloride fail there should be every reason for its being considered superior to, and preferred in ordinary usage to, either of these two well known styptics—to the former on account of its intrinsic cleanliness and to the latter on account of its greater safety Frequent applications to any part of the mouth, especially in a child, naturally render it liable for a larger dose of whatever drug may be employed to be swallowed than is perhaps justifiable, and calcium chloride if swallowed in reasonable doses is the very drug one would prescribe. It is into the hands of the great body of general practitioners that trying and anxious cases as the present one recorded first fall, and it is for such of these who may be, as I was myself, unaware of the unquestionable superiority at least in this instance, of calcium chloride as a local styptic over other styptics of more familiar name and repute, that I take the liberty of publishing this case

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

INTRA-UTERINE FRACTURE OF THE SKULL

By G W KILNER CROSLAND, M.R.C S ENG, L.R.C P LOND

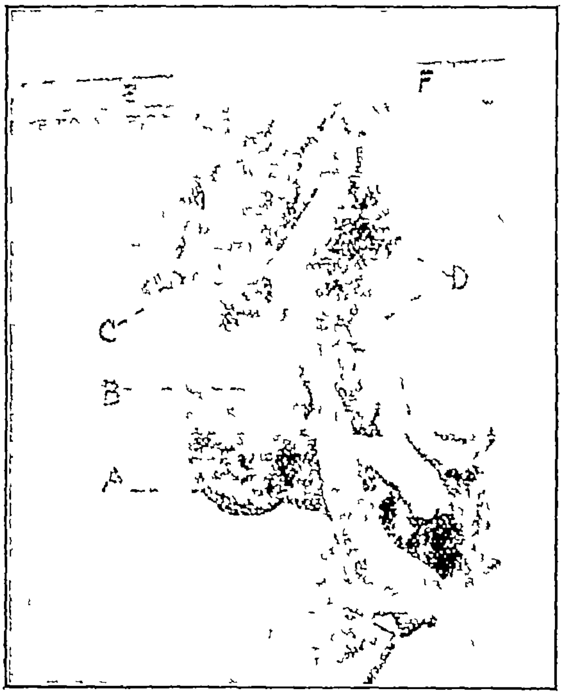
FRACTURES occurring in newly born children are chiefly interesting in their medico-legal aspect. The following case shows particularly well what a great amount of injury can be sustained by the child in utero without serious consequences to the mother and without premature labour taking place.

The patient was a multipara and was pregnant to term, of her fifth child The message was urgent and upon arrival I found that a precipitate labour had taken place and that a dead female child had been born, the mother having been delivered in a kneeling position upon the floor She informed me that four days previously she had fallen down the cellar steps, striking and severely bruising her back (the sacral region), at the time of the accident she felt very faint and the thought passed through her mind that her child was injured, there was no escape of either liquor amnii or of blood from the vagina. Four days later labour pains commenced and rapidly progressing the labour took place as stated above.

On examining the child a very curious and unusual condition was present she was dead, maceration and *post-mortem* change having commenced to take place. There was slight œdema of the feet and of the umbilical cord, the abdomen was flaccid, and the cuticle was commencing to peel away in places. On the left parietal region there seemed to be a cephalhydrocele but on examination this turned out to be a fracture or rather separation of the left parietal and the squamous portions of the temporal bone from one another and from the rest of the skull. They were both displaced or tilted outwards and the violence which had caused this had also displaced the brain in the same direction The lower jaw was fractured on the right of the symphysis. There was on both sides extensive orbital and subconjunctival ecchymosis It was evident that the severe injuries which had caused the death of the child were due to the head, resting in the normal position, being forcibly jammed as it were between two opposing sides of the pelvic brim probably the sacral promontory and the pubic bones There were no signs of syphilis, so-called fœtal rickets, or defective ossification which are said to be predisposing causes of this condition

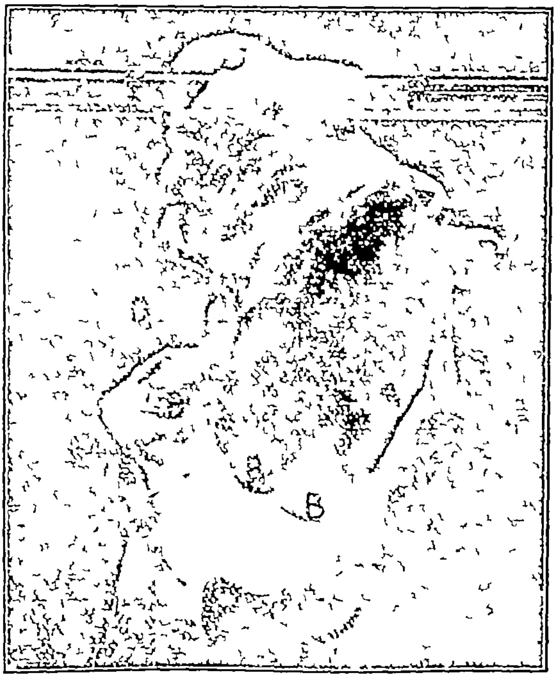
Injuries to the bones which are discovered in newly born children may be classified under three heads (1) those occurring before labour has commenced due to criminal or accidental violence, (2) those occurring during labour due to (*a*) disproportion between the child and the pelvis, (*b*) strong uterine contraction, and (*c*) unskilled assistance at birth, and (3) those occurring after birth, caused by (*a*) criminal violence and (*b*) accidental violence from precipitate labour inattention &c Cases which come under all these headings are described by various authorities on forensic medicine who seem to agree that those in the first group and affecting the cranial bones are very uncommon Casper in his handbook, after mentioning two cases, says "They compel us to assume that the child may be killed in utero by injuries to its cranium produced by violence inflicted directly upon the body of the pregnant woman, and, further Death from this cause is one of the rarest phenomena." Taylor, in his occurred and blood had leaked through it, causing a limited bulging of the fibrous coat of the aorta. The intima had thus lost the support of the fibrous coat and some slight exertion had led to a sudden enlargement of the opening—a tear, in fact, which would be immediately followed by the bursting of the fibrous saccule and fatal hæmorrhage into the pericardium. The aorta itself, even in the vicinity of the opening, was perfectly normal, and the valves and cavities of the heart, as well as the heart muscle, were quite healthy There were no vegetations or other signs of the action of micro-organisms The lungs and air passages were natural The heart had been repeatedly examined during life with the special object of excluding ulcerative endocarditis, and there had never been a murmur at any part of the cardiac area. There had been no impulse over the sternum, and the superficial and deep areas of dulness had been normal. The apex beat had been in its normal position

FIG 1.



A Sacculated swelling with linear rupture B Ascending aorta. C Reflexion of pericardium D Pulmonary artery laid open E and F Great vessels

FIG 2



A Triangular perforation in ascending aorta. B Aortic semilunar valves C Muscle and endocardium of the left ventricle D Pulmonary artery laid open E and F Great vessels

Many questions arise in the endeavour to explain the occurrence of an opening into a child's intra pericardial aorta Was it traumatic? Had the boy received a blow, or had he fallen and a stray pin or nail entered his aorta? There was no history of any such occurrence and no sign of any skin wound or puncture. Moreover, the object must have penetrated his sternum, since the swelling was situated immediately behind the sternum The inner aspect of the sternum was examined most carefully and there was not the least roughness or irregularity of any sort. One naturally looks for some connexion between this aortic perforation and the middle ear trouble for which the boy was under treatment The occurrence of an effusion into the left knee seemed to show that there had been some dissemination of septic material into the general circulation. The suggestion arises that there had been a small septic ulcer in the aorta the base of which had given way In that case it is hardly possible that the aortic and mitral valves, the cavities of the heart, and the rest of the aorta with its main branches should have remained entirely healthy Dr Tooth considers the aneurysm to have been undoubtedly of pyæmic origin, and the knee trouble to have been of the same nature The suggestion that the middle-ear suppuration was the beginning of the train of events seems to him the only reasonable one.

The specimen has been placed in the museum of St. Bartholomew's Hospital Dr F W Andrewes, pathologist to the hospital and curator of the museum, regards it as an acute infective aneurysm and suggests that, in the absence of any other evidence as to its causation, it may have originated as a localised septic aortitis, possibly due to a minute pyæmic embolus in one of the vasa vasorum. An embolus of this nature might occur in any small artery, in the present case it happened to occur in a very unusual situation and apparently in this one situation only

I publish these notes in the hope that they may bring to the mind of some reader a parallel instance or an explanation which will throw light on the present case

Leadenhall street, E C

A CASE OF HÆMOPHILIA ILLUSTRATING THE VALUE OF CALCIUM CHLORIDE AS A LOCAL STYPTIC

BY T WILSON PARRY, M A., M B, B C CANTAB.

IN the early morning of Sept 4th I was called to a boy, aged seven years and four months, who was bleeding from the mouth On examination, blood was seen to be welling up between the left lower first permanent molar and the temporary molar lying immediately in front of it the latter being decayed on its distal surface. Both of these teeth were firmly fixed. There was rapid oozing from the cleft and judging by the considerable clot that had been already evacuated from the mouth as well as by what still remained, there had evidently been continuous bleeding during the night So profuse and persistent did the hæmorrhage eventually become that the likelihood of there being more than one bleeding point was suspected and, accordingly, in consultation with my partner, Dr D McB Greig, a careful examination of the child's mouth and throat was made under an anæsthetic but no other source of bleeding than that already mentioned could be found. The inter dental fissure from which the blood flowed was so small that it was with great difficulty that the smallest fragment of wool could be packed into it. During the next four days however, I plugged it as efficiently as possible with minute pledgets of wool steeped in styptics of unimpeachable repute, to wit,

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON

Trauma and Infection at the Epiphyseal Line—Membranous Gastritis—Chronic Pancreatitis with Calculi—Stenosis of the Superior Vena Cava and of the Right Pulmonary Vein.—Primary Sarcoma of the Lung—Traumatic Rupture of a Bronchus.

A MEETING of this society was held on Feb 17th, Mr R. J GODLEE, a Vice-President, being in the chair

Mr H. L. BARNARD showed a series of specimens illustrating the Transition from Traumata to Infections of the Juxta-epiphyseal Line. He referred to the view chiefly supported by Ollier and other French writers that growing pains in children were the clinical expression of small hæmorrhages and trabecular fractures in those soft tissues. In conditions of latent pyæmia micro-organisms were supposed to circulate in the blood and if these escaped into the hæmatoma suppuration was liable to follow Two specimens were shown exhibiting small hæmorrhages in the epiphyseal line of the femora of patients who had not exhibited any sign or symptom of their presence before death, one, however, had leukæmia. Mr Barnard then endeavoured to explain the clinical varieties of infective osteitis—i.e., osteomyelitis, epiphysitis, and periostitis—by the position of the original lesion It was claimed that central lesions caused osteomyelitis, peripheral lesions periostitis and intermediate lesions epiphysitis.—Dr O F F GRÜNBAUM considered that there was positive evidence of the frequent existence of micrococci in the blood in many conditions and it was difficult to understand why suppuration did not occur more often than it did.—Mr. GODLEE asked for further information with regard to the hæmorrhages occurring in the epiphyseal line and as to their frequency in the post-mortem room. He mentioned the case of a youth who fell and struck himself in several places, in each of which an abscess subsequently developed.—Dr W S. LAZARUS BARLOW criticised the relation of growing pains to affections of the epiphysis. He stated that the high vascularity of the epiphyses would have led the observer to think that they would be less subject to infection than other tissues.—Mr. S. G. SHATTOCK asked whether every case of acute infective periostitis arose in the epiphyseal line He quoted some recent work on tuberculous infection of the bones and joints in which red marrow was regarded as the chief seat of infection.—Mr BARNARD replied.

Dr GRÜNBAUM showed the Cast of a Stomach vomited by a child, aged three years. The cast represented a complete lining of the stomach and consisted of a fibrinous network in which blood cells were entwined. Microscopically the only organisms found were staphylococci arranged in pairs. No bacilli were seen. This was contrasted with a cast removed from the pyloric end of the stomach of a child who had died from diphtheria in which case the pseudo-membrane was swarming with bacilli which had the form and arrangement suggestive of diphtheria bacilli. Attention was drawn to the fact that the membrane was vomited in two pieces, an interval of 18 hours separating the appearance of the first piece, which was the larger and which was from the cardiac end from the second piece, which was obviously from the pyloric end. This, said Dr Grünbaum was what might be expected from the fact that the majority of oxyntic cells were at the cardiac end and a certain degree of acidity would be required to loosen the pseudo-membrane from the gastric mucosa. The temperature of the child was subnormal during the illness the knee-jerks were absent and albuminuria was slight. After a rational rectal diet for ten days the stomach became tolerant and an uninterrupted recovery ensued.

Dr. T CHURTON showed a Pancreas in which there was complete Atrophy of the Epithelial Elements. The duct was lined with small calculi. The patient was a man, aged 41 years who had begun to lose flesh and strength three years before. Sugar was found in the urine when first examined one year before. The wasting of muscles was extreme but he was active until a few days before his death and perfectly conscious to the last hour There was never acetonuria. The quantity of urine was not great—from 80 to 100 ounces daily, the specific gravity was from 1023 to 1035. The quantity of sugar was from 1000 to 3000 grains and that of urea was from 300 to 550 grains There was no redness of the face or tongue, the sugar discharge was not lessened by codeia. The patient had been a furnace-man in an iron foundry and habitually drank cold water, even in winter when heated at work. He showed some signs of premature senility thick radial arteries and inelastic costal cartilages with deficient lateral expansion of the chest.—Dr JOHN F H. BROADBENT mentioned three cases of atrophy of the pancreas which he had recently seen. Two of these were in alcoholic subjects who had cirrhosis of the liver, the third was in a young individual with rapid wasting and glycosuria.—Dr CHURTON in reply quoted Lancereaux's statement that every case of diabetes in a lean person was pancreatic in origin. He doubted this statement as some of the nervous cases of diabetes also showed marked wasting

Mr. T W P LAWRENCE and Dr H. BATTY SHAW showed a specimen of Stenosis of the Superior Vena Cava below its junction with the Vena Azygos Major and also of the Right Pulmonary Vein. The specimen was found in a patient, aged 36 years. Five years before death he began to suffer from palpitation, dizziness faintness, dyspnœa, and hæmoptysis, he was sick after each meal and was thought to be suffering from phthisis. After about three months treatment he improved so much that he was able to resume his duties A second attack occurred 18 months after the first one and the same symptoms supervened, in addition the face had become very swollen and large veins had developed in the front of the chest and abdomen. A right-sided serous pleural effusion was found which recurred after aspiration. No further aspiration was performed and he was sent to convalesce in the country He improved somewhat and later was treated with potassium iodide, presumably because he had contracted syphilis 15 years before the onset of his first attack. He was, however, unable to return to work for the next 18 months, but in the summer of last year he was able to resume light duty in the City At this period he could not lace his boots owing to the dyspnœa produced by stooping, he was often sick after meals, and he rested at night propped up against pillows. In December, 1902, he was suddenly seized with great pain in his chest and was admitted to University College Hospital under the care of Dr J R. Bradford. Whilst in the hospital he grew steadily worse and he died on Dec. 30th, the œdema, which had been confined to the upper part of the body, spread to the abdomen and legs, there was a return of right pleural effusion, and the veins in the front of the body were very much dilated and filled from above downwards. At the necropsy the portion of the superior vena cava reaching from its junction with the vena azygos major to the auricle was found to be converted into a thick cord through which a small probe could be passed with difficulty, showing that the lumen was not quite obliterated. The entrance of the superior vena cava into the auricle was marked by dense white scar tissue. The single right pulmonary vein showed an annular stenosis where it was involved in an indurated mass, which also caused considerable thickening of the anterior wall of the left auricle, the anterior and upper part of the septum auricularum, and the inner wall of the right auricle. This mass of indurated tissue was continuous with that already noticed at the lower end of the superior vena cava. There were pericardial adhesions at the base of the heart and the right orifice of the transverse sinus of the pericardium was closed by adhesions. There was a further occlusion of the sinus transversalis towards its left end so that a closed cavity was formed of the right portion of the sinus Its wall was thick and composed of dense fibrous tissue, its inner surface was of a dull red colour and was coated with a loosely adherent inflammatory exudation of a purely fibrinous character The rest of the heart was normal. Both lungs were free from any sign of tuberculous disease and the mass of indurated structures above mentioned was continuous with the thickened pleura overlying the right lung and attaching the organ to the pericardium and chest wall and forming in the latter case an interpleural cavity from which a thin turbid fluid was removed. On section the right lung showed consolidation and collapse, the left lung being normal. The areolar tissue of the mediastinum was normal except where it was in relation with the pulmonary adhesions and the induration around the great veins above described, in these situations it was thickened, but there was no general chronic indurative mediastinitis. The case should apparently be classified as one of indurative mediastino-pericarditis, but it presented the peculiarity of being one in

"Medical Jurisprudence," quotes several cases, including one mentioned by Stanelli, very similar to the above. Fracture of the lower jaw in utero due to external violence applied to the mother seems to be of excessively rare occurrence.

Huddersfield

A NOTE ON THE CULTIVATION OF ANAEROBIC BACTERIA.

BY H. S FREMLIN, M R C S ENG, L R C P LOND

PLATE culture of bacteria under strictly anaerobic conditions by means of hydrogen is attended with considerable difficulty, as I have already shown in a paper on this subject.[1] On further experiments in anaerobic plate culture I have found that alkaline pyrogallic solution is much more satisfactory than hydrogen, if only a suitable apparatus be employed After several attempts I have devised such apparatus It consists of a circular glass chamber with a lid and is sufficiently large to hold an ordinary three and a half inch Petri dish. This chamber, which is five inches in diameter and one inch in depth, has a wide rim carefully ground. The lid of the chamber is flat and is ground at the margin so that when closed the ground surfaces of the lid and of the chamber are in accurate apposition In placing a Petri dish containing the inoculated medium within this chamber it is an advantage that the inoculated plate be put into another glass dish (as, for instance, the lid of a Petri dish) in order to prevent any splashing of the culture medium, or discolouration of the plate containing it, by the pyrogallic solution contained in the chamber The lid of the chamber must be well smeared with vaseline so that the apparatus is efficiently sealed after the lid has been applied The amount of pyrogallic solution required is the same as that ordinarily used for the cultivation of anaerobic bacteria in a Buchner tube Two tests, a chemical and a bacteriological, are applicable for ascertaining that anaerobic conditions have been secured and maintained in the apparatus. As a chemical reagent methylene blue may confidently be used. When the abstraction of oxygen is complete within such chamber as that described culture media contained in it that have been coloured with methylene blue become decolourised. For the bacteriological test bacillus tetani, as a strict anaerobic organism, may be relied on. The chamber in question is quite as suitable for plates that have been kept under aerobic conditions for some days as for plates just set up, the oxygen is extracted from the medium equally well in both cases A detailed account of this method will be found in the forthcoming report of the medical officer of the Local Government Board

Government Lymph Laboratories Chelsea Bridge S W

A NOTE ON A CASE OF BILATERAL LOCAL HYPERIDROSIS

BY G NORMAN MEACHEN, M D B S LOND, M.R.C P LOND, M R C P EDIN,

PHYSICIAN TO THE SKIN DEPARTMENT, TOTTENHAM HOSPITAL N

A BOY, aged 14 years attended at the out-patients' department of the Tottenham Hospital with an irritative dermatitis of the skin over the abdomen due to pediculi when it was accidentally discovered that beads of sweat were standing out upon the tip of his nose On closer inspection the hyperidrosis was seen to be limited to the integument over the dorsum of the tip of the nose and to the two alæ nasi, corresponding to the distribution of the external terminal branches of the nasal and maxillary division of the fifth nerves of both sides The sweating area was slightly erythematous and covered with numerous small telangiectases The skin over the bridge of the nose, as well as that of the rest of the face, was quite dry The condition had been noticed for a year and was practically constant, being apparently uninfluenced by emotional or meteorological changes. He had had no previous illnesses There were no other cutaneous abnormalities present and the other systems of the body were normal.

The chief interest of this case lies in the unusual situation for a local hyperidrosis, its bilateral character, its persistence, and the absence of any apparent cause, such as neurosis or a nerve lesion

New Cavendish street, W

A NOTE ON THE USE OF CARBOLIC ACID IN THE TREATMENT OF SMALL-POX.

BY JAMES T NEECH, M D DURH., D P H. VICT,

MEDICAL OFFICER OF HEALTH AND MEDICAL SUPERINTENDENT OF THE BOROUGH FEVER HOSPITALS, HALIFAX

ALTHOUGH it appears that various local applications have been used in the treatment of small pox, and among them dilute carbolic acid, I can find no record of the pure acid ever having been used for that purpose. The use of the acid when applied early in arresting the development of boils and the excellent results I have obtained in the past in the treatment of certain pustular eruptions of the skin led me to think of trying it in this disease This idea struck me at least two years ago but I never had the opportunity of trying it till recently The very limited experience I have had of it so far is so encouraging and in one case I think so remarkable that I determined to make a few remarks on the matter that others who have a much larger number of cases of this disease under their care may try this remedy if they think fit to do so The method adopted was to apply carefully with a small camel hair brush the pure acid to the rash over a certain area of the body each day, the face and head being the area selected for the first day

The first case so treated was that of a girl, aged 12 years It was the seventh day of the eruption—viz, Jan. 24th—and the vesicles were beginning to become pustular The result was that the vesicles either dried up into crusts without becoming fully pustular, or, as happened in many cases, the contents of the vesicles became absorbed and the epidermis inclosing the vesicle scaled off. During this process the girl, who had been very ill, felt well and her temperature was normal The vesicles all scaled off within five days, leaving the usual marks but no pitting

The second case was that of a male, aged 54 years, and the disease was confluent In this case there was a diffuse red rash all over the body and the face was swollen to such an extent that he was scarcely able to see. There was also delirium It was impossible to apply the carbolic acid in consequence of the character of the rash until the vesicles appeared, which they did on Jan 28th, when the application to them of the acid was commenced as before over the face and head This treatment was assiduously persisted in till the rash over the whole body had been treated, with the result that pustulation was averted The swelling of the face gradually subsided and the man improved daily, the temperature first falling to normal on the morning of Feb 2nd In this case also after treatment the serum in the vesicles either exuded and dried up into scabs or became absorbed and the epidermis peeled off

The same treatment has been applied to two other mild cases in different stages and as far as one can judge from so limited an experience the application of carbolic acid will arrest the disease either in the papular, vesicular, or pustular stage. The second case recorded above was severe and confluent. The treatment cut short the disease, the second suppurative fever was averted there will be no pitting, and the offensiveness of the pustular stage was prevented, and in my opinion the infectiousness of the patient was very materially diminished In conclusion I have to acknowledge the valuable assistance which Mr C G Foggo rendered me in carrying out the treatment and in watching the cases

Halifax

TAUNTON AND SOMERSET HOSPITAL — The annual meeting of the governors of this institution was held on Feb 11th. The medical report stated that 901 in patients were admitted during 1902, compared with 824 in 1901. The out-patients numbered 4311, against 3968 in the preceding year The financial statement showed that the income amounted to £4771 and the expenditure to £4958, leaving an unfavourable balance of £187 The donations received during the year included £200 from Mr Proctor Baker who was elected president for the ensuing year been able to accomplish even in the post-mortem room.—Mr SPENCER replied that he was, of course contemplating cases in which the ligaments of the joints were more or less disorganised and relaxed and he agreed that it would hardly be practicable in a normal joint.—Mr SHEILD added that in all his cases the joint was distended with turbid serum containing large flakes and lumps of purulent lymph rich in gonococci

---

[1] See Report of Medical Officer of the Local Government Board 1900–01, pp 617-619

Dr A. STANLEY BARNES (introduced by Sir WILLIAM GOWERS) read the notes of a case of "Local Panatrophy" which he (Dr Barnes) believed in its clinical relationships lay midway between the case shown by Dr Harry Campbell on Oct. 24th, 1902,[1] and that exhibited by Dr T D Savill on Jan. 23rd, 1903,[2] at that society The patient at the age of 24 years was thrown from a horse and at 25 years fell on the back of her head whilst skating At the age of 32 years she first began to have facial neuralgia, and at 34 years she noticed a difficulty in raising the left arm. She was seen about that time (1884) by Sir W Gowers who found atrophy around the shoulder and in numerous other places on the surface of the body At the present time, the patient now being 52 years of age, patches of atrophic skin were to be found on the face and in many other situations. There was also a partial right facial palsy, possibly due to implication of the facial nerve in one of the atrophic patches. Over the largest of the patches the subcutaneous tissue and the muscle were wasted, and in one patch the subjacent bone was also atrophied. The skin was soft, thin, and devoid of hairs, there was no anæsthesia, and there was no reaction of degeneration in the muscle beneath. —Dr T D SAVILL remarked on the interest of the case which, like the cases exhibited by Dr Harry Campbell and by himself, he regarded as belonging to the class of morphœa atrophica described by the late Sir Erasmus Wilson The atrophy might be very considerable and involve the subjacent tissues He (Dr Savill) had lately seen a patient in whom the patches, at first resembling morphœa lardacea (sclerodermia) had after eight years become atrophic like those under consideration The history of injury and neuralgia in Dr Barnes's case tended to confirm the idea that the disease was of neurotrophic origin.—Dr POORE alluded to a patient under his care who presented patches of atrophic skin on different parts of the body, evidently of the same nature as those described and who also exhibited curious recurrent patches of local dilatation of the blood vessels on the fingers.—Dr BARNES, in reply, stated that no evidence of vascular disturbance had been discovered in this case. The neuralgia from which the patient suffered was bilateral. He adhered to his statement that the patient was suffering from paralysis of the face and gave his reasons for that belief There was a total absence of any sclerosing tendency in the skin lesions.

OBSTETRICAL SOCIETY OF LONDON

Fœtal Ascites —Profuse Meningeal Hæmorrhage during Labour —Primary Carcinoma of the Fallopian Tube —Sarcoma of the Ovary —Exhibition of Specimens —Reports of Officers —Presidential Address

THE annual meeting of this society was held on Feb 4th, Dr PETER HORROCKS, the President, being in the chair

Dr T W EDEN showed a specimen of Fœtal Ascites The patient, aged 18 years, was admitted to one of the workhouse infirmaries in London on Jan 17th, 1903, having then been for some hours in labour On admission it was noted that the external os was of about the size of half a-crown, the membranes were ruptured and the presentation was a footling Pregnancy had advanced to about the end of the eighth month. The progress of the labour was very slow, and on the morning of the 18th one drachm of liquid extract of ergot with one ounce of brandy was given and repeated twice during the course of the day At 8 P M the foot of the child was found in the vagina in the words of the medical attendant "quite black and putrid.' Traction upon the limb was made to deliver the breech but the foot separated at the ankle The remainder of the limb was then seized, but it soon separated at the hip-joint. Traction upon the other leg failed in the same way Then an attempt to seize the breech was made with a pair of craniotomy forceps, but 'every time traction was made they came away with a piece of putrid skin." Being unable to make out the cause of obstruction, the medical attendant sent for assistance. A distended abdomen was found to form the presenting part and to be the cause of the obstruction to delivery It was opened with a pair of scissors, and between two and three quarts of thin yellowish fluid escaped The body of the child was delivered naturally within a few minutes The placenta was adherent and had to be removed by the fingers. The body of the fœtus showed marked signs of maceration On laying the abdomen open the peritoneal cavity was seen to be enormously enlarged, the liver the stomach and the intestines were crowded into the vault of the diaphragm, there were neither peritoneal adhesions nor any signs of peritonitis in any part. The heart was normal, there was no distension of the ureters, and the kidneys were normal. The liver and portal circulation appeared to be normal. There was no syphilitic history The cause of the ascites was obscure. The mother made a good recovery —Dr HERBERT R. SPENCER had met with about six cases of fœtal ascites In some of these the amount of fluid was small but there was a large amount of lymph binding the intestines together and the absence of any obvious cause for this peritonitis and the presence of bone disease and the history had led him to think that in these cases the ascites was due to syphilis —Dr E. MALINS was inclined to think that syphilis was adduced generally in the absence of other known or ascertained causes

Dr A. W SIKES brought forward a short communication on a case of Profuse Meningeal Hæmorrhage during Labour and this was discussed by Dr SPENCER and the PRESIDENT

Dr H. RUSSELL ANDREWS read the notes of a case of Primary Carcinoma of the Fallopian Tube, and some interesting points in regard to the disease were brought forward by Mr ALBAN H. G DORAN and Dr J INGLIS PARSONS.

Dr PARSONS read the notes of an unusual case of Sarcoma of the Ovary

Mr HANDLEY showed a specimen of a Solitary Interstitial Fibroid removed by abdominal myomectomy

Dr SPENCER exhibited Kurz s ingenious Needle Holder

The reports of the treasurer, of the librarian, and of the chairman of the Board for the Examination of Midwives were then received and ordered to be printed in the Transactions of the society, the different officers being thanked for their services.

The PRESIDENT, in delivering his address, referred to the passing of a law whereby legally qualified ladies were made eligible for the Fellowship of the society and the names of ten ladies who had been elected during the past year were given It was also pointed out that a new rule had been made to enable authors of papers to have their work published in journals other than in the Transactions of the society if they so desired. The financial condition of the society was satisfactory Now that the Midwives Act had been passed the necessity for continuing the examination held for midwives by this society would shortly cease to exist Dr F H. Champneys was congratulated on being elected chairman of the first board appointed by the State and the State was to be congratulated on having secured the services of one who knew the work so well and who was second to none in ability for organising the new State examinations on a thoroughly satisfactory basis. The new pathological committee, instituted 12 months ago, had done excellent work. Allusion was made to the excellent material provided by the exhibition of 59 specimens during the past year Nine papers had also been read during the year, and a brief *résumé* of each paper was given, the salient points of each subject being commented upon together with the general opinions which were given during the discussions. Obituary notices of Fellows who had died during the preceding year were given—namely, of Mr John Griffith Lock of Tenby, of Mr John James Tweed of London, of Dr Thomas Robert Lombe of Torquay, who was elected a Fellow in the year of the foundation of the society 1859, of Mr James Neal of Birmingham, and of Dr Henry Oldham, consulting obstetric physician to Guy s Hospital. Dr Oldham was one of the first vice-presidents of the society and was its third President and its second treasurer and one of its first three trustees He held the latter post up to his death, that is, for a period of over 40 years. Dr Champneys had been appointed in his stead Dr Oldham was appointed obstetric physician to Guy's Hospital at the same time as was Dr Lever He was one of the best lecturers that Guy's Hospital ever had Interesting details of his life were given, obtained from Sir Samuel Wilks, Dr Constantine Holman, Colonel which the change was markedly localised, and in view of the previous history of syphilis the possibility presented itself of the disease having originated in a gumma around the great veins of the heart.—Dr A. E GARROD stated that most of the recorded cases of indurative mediastinitis were associated with right-sided pleurisy He referred to a case recorded by Sir Dyce Duckworth and himself of total occlusion of the superior vena cava, an interesting feature of which was that there was no swelling of the head or neck He also referred to another case of narrowing of the superior vena cava with swelling of the head and neck.

---

[1] THE LANCET Nov 1st 1902, p 1196

[2] THE LANCET Jan 31st 1903 p 303.

Dr E P BAUMANN and Dr F A. BAINBRIDGE showed a specimen of Primary Sarcoma of the Lung from a girl, aged three years and 11 months, who was admitted into the Hospital for Sick Children, Great Ormond street, under the care of Dr D B Lees on June 30th, 1902, as a case of empyema. The illness had begun six weeks before with headache and abdominal pain and during its course the child had become greatly emaciated, a cough developed and several attacks of hæmoptysis occurred. The past history and family history were unimportant On admission the case appeared to be a clear one of effusion into the left pleura, with dulness over the whole left side of the chest and absence or deficiency of the breath and voice sounds, bulging of the intercostal spaces, and displacement of the heart to the right. The temperature was 101 4° F, the pulse was 132, and the respirations were 68 Repeated aspirations and an exploratory incision resulted only in the withdrawal of a little blood stained fluid containing on one occasion fragments of cheesy débris, these gave negative results on examination for malignant disease, tubercle, and other organisms The temperature remained high and irregular The child became rapidly worse and death occurred on July 12th, a fortnight after admission The whole duration of the illness was eight weeks. At the necropsy the upper lobe of the left lung was found replaced by a soft growth which microscopic examination showed to be a sarcoma. The lower lobe was collapsed and firm, but showed no traces of the new growth The left pleura was adherent and thickened but was not invaded by the growth. The bronchial and mesenteric glands presented a healthy appearance and no other tissues or organs were involved The post-mortem records of the Hospital for Sick Children from January, 1860, to the present day did not furnish a single other instance of the occurrence of primary sarcoma of the lungs

Mr GODLEE showed a card specimen of Traumatic Rupture of a Bronchus without Fracture of the Ribs or other Inter thoracic Injury

CLINICAL SOCIETY OF LONDON

The Drainage of the Knee joint in Acute Suppurative Arthritis —A Case of "Local Panatrophy"

A MEETING of this society was held on Feb 13th, Dr G VIVIAN POORE, a Vice President, being in the chair

Mr H L. BARNARD communicated a paper on the Drainage of the Knee joint in Acute Suppurative Arthritis, illustrated by nine cases He commenced by considering various operative procedures which had been adopted from time to time such as those of the late Mr Walter Rivington and Mr Walter Whitehead Mr Barnard pointed out that few cavities of the body were so difficult to drain as the knee joint The usual method by lateral anterior incisions drained only the anterior half of the joint The anatomy of the knee joint showed two capacious pouches behind which reached above the condyles posteriorly where they were covered by the heads of the gastrocnemius They were separated from one another by a complete septum formed by the crucial and other ligaments The external pouch sent a bursal extension down the leg along the tendon of the popliteus. When the knee-joint was extended these two pouches were shut off from the front of the joint by the tight coaptation of the femur and tibia. When distended with pus they ruptured into the depths of the popliteal space, where the sepsis was liable to involve the vein. The abscess then tracked down the calf and up the thigh making drainage of both tracks almost impossible. The pouches should be freely opened by two inch incisions in the line of the leg made by cutting on the condyles where they could be felt projecting on either side of the popliteal space when the leg was fully extended. In order not to wound nerves, when the skin had been divided a blunt instrument should be used to scrape down to the capsule which might then be freely divided with the knife. The knee was then flexed to relax the structures and tubes were inserted on each side. In eight of the nine cases treated by this method the temperature fell to normal in from 36 hours to a week. Massage — downward in front and upward behind — greatly assisted the evacuation of pus from the deep pockets. The nine cases given in the paper were consecutive The four traumatic cases gave the best results Two had good movement, one had some movement, and one had fibrous ankylosis. The five cases of auto-infection were less satisfactory, two were amputated, one for feeble repair and persistent sinuses, in an old woman, aged 65 years, and the other for a tuberculous cavity in the end of the femur infected with erysipelas Two cases apparently due to leucorrhœa were most unsatisfactory It was claimed that the method of posterior drainage would cope successfully with the immediate dangers of sepsis The final condition of the joint depended rather on the cause of the suppuration Subacute cases of suppurative arthritis of the knee due to auto infection should be treated by the usual lateral patellar incisions and irrigation —Mr W G SPENCER observed with regard to the posterior pouches of the joint that if they were opened from behind there was much more danger of injuring the popliteal nerves than if opened by cutting down upon a probe or sinus forceps Discussing the merits of the open method he related a case on the verge of delirium tremens in which an injury to the knee joint was followed by necrosis of the patella and suppuration In this case he opened the joint freely and recovery ultimately followed with the joint ankylosed in the middle position. He regarded the open method as a preferable alternative in cases that would otherwise have to be treated by amputation.—Mr H. H. CLUTTON advocated small lateral incisions and washing out the joint, followed by immediate suture, a method which had given excellent results in a number of cases usually treated by more energetic measures The joint could be digitally examined. The infecting microbe could be investigated He thought that some of Mr Barnard's cases, although acute, might have been treated in this way Acute cases had been very satisfactorily treated by this method.—Mr A. MARMADUKE SHEILD remarked that the pouches of the knee joint were very inconstant in their position and communications He also claimed that the good results related by Mr Barnard were not confined to the London Hospital but that elsewhere acute suppurative arthritis was generally recovered from with movement of the joint, especially in young and otherwise favourable cases Age was an important factor He referred to five cases of his own of acute gonorrhœal infection of the knee joint treated by one incision on the inner side of the patella and flushing with a solution of biniodide of mercury, the wound being closed at once, with very good results In four complete, and in the fifth almost complete, movement was obtained. He recalled the striking results obtained by Dr J O Conor of Buenos Ayres with this method of treatment. This surgeon, indeed, went a step further, for he treated in the same way joints with what was generally described as rheumatic effusion but which in many instances were obviously nothing of the kind, being of the nature of a pyæmic infection such as occurred in puerperal women and after neglected abortion Similar septic suppuration was met with in servants who lived in badly drained houses. Mr Sheild thought that in some cases drainage might be done advantageously through posterior incisions but advocated the employment of large tubes with thorough irrigation of biniodide of mercury solution (1 in 1000) —Mr F C WALLIS referred to three cases of gonorrhœal effusion into the joint which he had opened and washed out with normal saline solution with extremely satisfactory results, in that the patients recovered with perfectly moveable joints He did not think that it was good practice to wash out the joint with strong antiseptic solutions, which tended to irritate further the synovial membrane.—Mr BARNARD, in reply, pointed out that he only advocated the posterior incisions in very severe cases, especially in cases of suppurating wounds of the knee or wired patella cases which went wrong He asked Mr Sheild whether there was pus in all his cases, in view of the fact that the great majority of these cases got well without any incision at all. He asked Mr Spencer whether he or anyone had ever succeeded in introducing a probe or sinus forceps into the posterior pouches from the front, a feat which he himself had never of the operation was much less frequent now than it was in the old days, partly because anæsthetics abolished pain which was an important factor in the causation of shock, and partly because they protected the central nervous system from receiving impressions of the serious damage which was being done to the tissues by the operation Shock was a reflex phenomenon, but the relation of anæsthetics to shock differed from their relation to the other reflexes in that whereas they could only abolish the latter they could both abolish and also produce shock or a condition exactly resembling it. Dr Blumfeld was of opinion that since both shock and deep chloroformisation were characterised by a marked fall in blood pressure a deep degree of anæsthesia should as far as possible be avoided in operations upon patients already suffering from shock or likely to suffer from it as a result of the operation. There was, however, no evidence to show that ether produced shock in the same way as chloroform although it often gave rise to collapse after a prolonged administration of large doses in the kind of case referred to The surgeon was apt to forget the immense importance of economising the time during which parts of the body such as the bowels, for instance, were being subjected to manipulation, for the longer such procedures lasted the more easily was shock induced. The purely nervous element had also to be taken into consideration and added greatly to the difficulty of determining the cause of shock. Dr Blumfeld here quoted undoubted cases of shock from nervous influence. In a letter on the Surgical Treatment of Perforated Typhoid Ulcer,' published in THE LANCET of Jan. 17th, p 199 Mr H. J Curtis had raised the question of anæsthetics and had advocated the use of local anæsthesia, assuming an extra danger from general anæsthesia in these cases. Dr Blumfeld believed that the society was not prepared to admit this assumption but that it was in a position to say with regard to such cases that if an operation must be performed there was less danger in performing it if a general anæsthetic were properly given than there was in performing it without one.—Mr Curtis said that if the perforation were doubtful and an exploratory operation were undertaken he preferred local analgesia, but if the perforation were undoubted then a general anæsthetic was much to be preferred, and he merely suggested local anæsthesia as a compromise in those cases where it was thought that a patient ought to have the benefit of the doubt of an exploratory operation, but where the intrinsic risk of a general anæsthetic had to be avoided. He had seen Cæsarean section performed under local anæsthesia with no pain or trouble except when the vessels were caught in the clip forceps.—Mrs F M. Dickinson Berry M D, and Miss L B Aldrich Blake, M.D, said that they had seen many operations for goitre performed under local anæsthesia without any symptom of shock.—Mr H O Crouch was emphatically of opinion that shock was far more likely to supervene under light than under deep anæsthesia, that his practice was to push the anæsthetic to its fullest extent, and that he taught that fall of blood pressure from chloroform was much less dangerous than fall of blood pressure from shock.—Dr Harold Low said he constantly observed that when the fear of the operation which caused symptoms of shock, was removed by the administration of an anæsthetic the patient's condition markedly improved and the symptoms of shock disappeared, this was especially the case under ether —The President said that after an experience of 25 years he felt that there were cases in which shock was produced under light anæsthesia and also cases in which the shock was more marked under profound anæsthesia. Each case had to be treated according to circumstances.—Dr James Maughan reported a case of Death following the Administration of Nitrous Oxide. The patient was a young woman who was suffering from tonsillitis but in whom the constitutional symptoms were marked and the pulse rate was out of all proportion to the physical signs Dr Maughan administered nitrous oxide as she would not allow him to incise the tonsil without an anæsthetic. She was placed in an easy chair in her nightdress with a prop between the teeth Anæsthesia was quietly induced to the stage of loss of light reflex, two breaths of air having been given with the gas. At this point the face-piece was removed but precisely at this moment the patient was observed to have stopped breathing She was immediately placed on the floor with the forceps upon the tongue, Howard's method of artificial respiration was tried for about 15 seconds, ammonia being held to the nose meanwhile, but no air entered, no further time was therefore lost, Dr Maughan promptly performing laryngo-tracheotomy, when a full deep inspiration was taken, the lips and cheeks quickly returning to their normal colour The corneal and conjunctival reflexes were, however, absent and never returned. The radial pulse was small, quick, and barely perceptible, the respirations were about 12 per minute and so continued for 15 minutes when the intervals began to enlarge and the inspirations to become shallow The breathing became more and more irregular during the next ten minutes when the patient died, the pulse during the last ten minutes of life becoming imperceptible at the wrist, although the heart sounds could be heard up to the last moment. The post-mortem examination revealed nothing beyond extensive angina Ludovici and some œdema of the glottis The mitral orifice of the heart was rather smaller than normal but there was no evidence of structural damage either recent or remote Dr Maughan was at a loss to explain the cause of death since the tracheotomy prolonged life for 19 minutes, he therefore asked for the opinion of the society He regretted that he had not used a local or a very light chloroform anæsthesia, but he thought that in a rapidly progressive disease of this kind affecting the respiratory organs no anæsthetic could be deemed harmless —Dr R. J Probyn Williams agreed that in such circumstances nitrous oxide gas was certainly not harmless, but in this case he could not see that the death was due to the gas since the patient lived for 19 minutes after the administration was stopped and the air way was rendered clear by the operation of tracheotomy —Dr Low related a similar case in which he had been called upon to give chloroform, he was using the lightest possible degree of anæsthesia but the patient became so ill that he stopped the administration and the patient recovered sufficiently to be able to answer questions, only to die a few moments later He pointed out that if this patient had not spoken the death would have been attributed to the chloroform.—The President agreed that the case could not be attributed solely to the anæsthetic, and there was no doubt that the patients in these acute cases of septic throat died very suddenly He could not see what more Dr Maughan could have done for the patient. He thought that probably the true explanation was that the patient died from heart failure due primarily to the septic infection but hastened by the anæsthetic.

MANCHESTER MEDICAL SOCIETY —A meeting of this society was held on Feb 4th.—Dr A M. Edge delivered his Presidential Address on Diagnosis and Some of its Difficulties After some preliminary observations the President commented on the necessity, when examining a case, of using the knowledge which might be gained by careful observation of the patient's expression, attitude, &c. He deprecated having recourse to bacteriological methods of diagnosis until a thorough examination of the patient had been made and an opinion had been formed thereon. An exception was made however, in the case of suspicious sore-throats, in which he advised an examination for Löffler's bacillus at the earliest possible moment. He went on to say that the term "diagnosis" when used in its widest sense included etiology, prognosis, and treatment and he gave illustrations in support of the statement. Some of the causes of failure in diagnosis were then enumerated, such as absence of previous history, haste, carelessness, and attaching too much importance to a single symptom Incomplete diagnoses were also referred to and several cases were mentioned as instances But after excluding all such causes of difficulty and failure the President stated that there would always remain a large number of cases in which diagnosis was frequently impossible from their very nature, giving as an example the group of affections termed, from an important symptom, obstruction of the bowels. The President concluded by a reference to the wonderful advance in diagnostic methods which had occurred during the last quarter of the nineteenth century —Dr P H. Mules communicated a paper on Some Toxins in their Relation to the Eye and its Appendages. The following cases were described. 1. A case of Retro-bulbar Neuritis with complete blindness of the right eye of a young woman aged 28 years, who 19 years previously had suddenly and persistently lost her hearing on the same side. The toxins of inherited syphilis were considered to be the cause Mercurial inunction and full doses of quinine were followed by return of the vision to J 1 and $\frac{6}{12}$ but there was persistent disc pallor The hearing returned to one fourth of

Oldham (his surviving son), and others Thanks were given to the senior honorary secretaries, Dr Spencer and Dr Amand J M. Routh, who had greatly assisted the President during his first and second years of office respectively

A vote of thanks to the President was moved by Mrs. M. A. D SCHARLIEB and seconded by Mr DORAN and carried unanimously

The list of officers for 1903 recommended by the council was read

A vote of thanks to the retiring vice president and members of the council was moved by Dr C HUBERT ROBERTS and seconded by Dr F G BLACKER.

Dr C J CULLINGWORTH moved and Dr EDEN seconded, that the cordial thanks of the meeting be given to Mr Doran for his valuable services to the society as editor of the Transactions, which office he had now resigned

This was carried with acclamation and was acknowledged by Mr DORAN

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM

Tuberculosis of the Ear, the Nose, and the Naso pharynx

A MEETING of this society was held on Feb 2nd, Dr URBAN PRITCHARD, the President, being in the chair A discussion on Tuberculosis of the Ear, the Nose, and the Naso-pharynx was opened with papers by Dr V H. WYATT WINGRAVE Dr W JOBSON HORNE, and Dr W MILLIGAN

Dr WYATT WINGRAVE read a report upon the Microscopical Examination of the Discharge in 100 cases of Middle ear Suppuration, with an Analysis of the Results, having special reference to the presence of tubercle and "acid fast" bacilli. He arrived at the following conclusions (1) that acid- and alcohol-fast bacilli were demonstrable in a large proportion of chronic purulent ear discharges, (2) that in 17 cases they were presumably tubercle bacilli, in so far that they conformed to the recognised morphological and staining characters, and were for the most part associated with trustworthy clinical evidence of tuberculosis, (3) that in seven (pseudo-tubercle bacilli) cases, while conforming in a greater or less degree to the staining requirements, they were morphologically unlike tubercle bacilli, yet five of them had either a family or personal history of phthisis, (4) that success in their demonstration in a great measure depended upon the methods of collecting and staining together with perseverance in search, and (5) that in the peculiar selective action of the squames—a property specially attributed to certain bacilli—they had a possible source of error in diagnosis and an explanation of the peculiar affinity of other bacilli for fuchsin.

Dr JOBSON HORNE read a paper on the Clinical Diagnosis and Surgical Treatment of Tuberculosis of the Temporal Bone considered with reference to the Pathology and Morbid Anatomy of the Disease. The paper so far as it related to the clinical diagnosis, after taking into account the characteristic features of tuberculosis of the ear dealt mainly with two points (1) the value to be attached to circumstantial evidence in the absence of positive proof of the nature of the disease, and (2) the necessity for discriminating between primary and secondary infection of the ear The surgical measures and the limitations to be put upon such measures were to be decided by ascertaining this second point. Caution was expressed against regarding suppurative disease of the middle ear occurring in a tuberculous subject as necessarily tuberculous in nature. It was held that the detection of the bacillus tuberculosis was the only proof positive of the disease being tuberculosis The existence of a group of 'acid fast" bacilli other than the bacillus tuberculosis did not invalidate the microscopic diagnosis of the disease, provided the ordinary requirements of bacterioscopic technique were complied with Negative evidence was of no value, failure to detect the bacillus tuberculosis did not prove the disease to be non tuberculous nor did it disprove the possibility of it being tuberculous. The difficulty in detecting the bacillus in the discharge was discussed A theory was advanced which would at once explain both this difficulty and a well known clinical feature of the disease—absence of pain and also the correlation of these two clinical phenomena The theory was based upon the fact demonstrated by Dr W Bulloch and Dr J J R Macleod that the "acid fast" property was due to a wax like body in the bacillus and not to a fat, that the wax when broken up set free an alcohol which was an essential factor in the staining property It was suggested that the decomposition of the wax was accountable for the difficulty in detecting the bacilli and the resulting product possessed an anæsthetic property The differential diagnosis between primary and secondary infection could be made partly by the exclusion of tuberculosis existing in other organs, but more particularly by the condition of the glands adjacent to the affected ear, in the primary infection the glands were more often and more extensively involved. As regards treatment, the surgical ablation of disease secondary to pulmonary disease was to be avoided, but in the primary form it was to be undertaken by removing in the first instance the infected glands, the possibility of the occurrence of a blood infection and of death from miliary tuberculosis was to be kept in view

Dr MILLIGAN read a paper on the Diagnosis and Treatment of Tuberculous Disease of the Middle Ear and its Accessory Cavities. The paper dealt fully with the subject and the conclusions arrived at were as follows 1 That in all cases of middle ear disease of suspected tuberculous origin search should be made for tubercle bacilli either in the discharge, in tufts of exuberant granulation tissue, or in enlarged periotic glands. 2. That inoculation experiments (either subcutaneous or intra peritoneal) afforded a ready and trustworthy means of proving or excluding the tuberculous nature of the disease 3 That a final and exact diagnosis was imperative both from the point of view of prognosis and of treatment 4 That tuberculous disease of the middle ear and accessory cavities was a frequent disease amongst infants and young children 5 That the disease was most frequently found as secondary to tuberculous processes in other regions of the body 6 That primary tuberculous disease of the middle ear was probably of more frequent occurrence than was usually supposed 7 That the prognosis was always grave, but that in a certain proportion of cases suitably planned surgical intervention would eradicate the disease 8. That in many cases it was advisable to conduct the operative treatment "in stages" 9 That when less than 10 per cent of hearing power remained no attempt should be made to preserve the organ as an organ of special sense 10 That when more than 10 per cent. of hearing power remained in a patient, in otherwise apparent health, a definite attempt should be made to preserve what amount of hearing power still existed. 11 That where the tuberculous origin of the disease had been scientifically demonstrated the case should be regarded as infectious and precautions taken accordingly

A discussion, in which the PRESIDENT, Mr C A. BALLANCE, Mr A. E CUMBERBATCH, Dr A. L WHITEHEAD, Dr HUGH E. JONES, and Mr A H. CHEATLE took part, was adjourned until March 2nd

SOCIETY OF ANÆSTHETISTS —A meeting of this society was held on Feb 6th, Mr Walter Tyrrell, the President, being in the chair —The President, referring to the case of death following an administration of nitrous oxide gas, a newspaper report of which he read at the last meeting of the society, said that on investigation he had found it to be a death not from nitrous oxide gas but from acute ammonia poisoning, strong ammonia having been held to the nostrils of the patient for about ten minutes after the administration by the dentist who had given the gas, as the patient did not seem to be recovering in the usual way The patient was removed to hospital and died some 13 hours after the administration —Dr Joseph Blumfeld read a paper entitled "The Relation of Anæsthetics to Shock" and said that his object was to raise a discussion upon the question of the part which anæsthetics played in the prevention of shock, he was aware that exactly opposite opinions were held on this point, some observers believing that the shock which was present after certain operations was due entirely to the anæsthetic and others believing that it was due entirely to the operative procedures and would be much worse without the anæsthetic. He also referred to the difference of opinion with regard to shock and the depth of anæsthesia, some anæsthetists holding that shock was more commonly met with in light than in deep anæsthesia and others holding exactly contrary views. In speaking of shock he also included collapse, for both were conditions of prostration in which failure of the circulation played a prominent part. Death from shock thanks to the President for his address, proposed by Dr C H. F Routh and seconded by Mr Jessett, was put to the meeting by Dr Macnaughton Jones and carried by acclamation.

Incorporated Society of Medical Officers of Health.—A meeting of this society was held on Feb. 13th, Dr. Arthur Newsholme, a Vice-President, being in the chair —Dr E W Hope, medical officer of health of Liverpool, opened a discussion upon the Renewal of the Vaccination Act He urged the desirability of transferring the administration of the Vaccination Acts from boards of guardians to sanitary authorities and said it was anomalous that the only certain means of safeguarding the public from the dangers of small pox should not be in the hands of that body which was responsible for the public health. He insisted upon provision being made for an adequate supply of lymph and suggested that depôts should be established in various parts of the country where lymph could be manufactured and supplied On the question of giving false information or withholding information relating to small pox when asked by the proper authority Dr Hope quoted with approval a clause in the Liverpool Corporation Act, 1900, which made the occupier of a house liable to a penalty if he either refused information or gave false information relating to any person resident in the house who was or had been suffering from a dangerous infectious disease.—A series of motions which had been previously discussed at branch meetings and by the council of the society were brought before the meeting and with slight alterations were agreed upon. These resolutions expressed the opinion of the society that every child should be vaccinated before he or she was six months old, that any relief from this requirement should be by empowering magistrates to suspend vaccination for a definite period and not by unlimited exemption as at present, that a renewal of exemption should be applied for when a child reached the age of four years and again when he or she was 12 years old, that revaccination at 12 years should be required, that the Local Government Board should be empowered to require revaccination at an earlier age than 12 years in infected localities, that all "contacts" should be required to be vaccinated or revaccinated forthwith if the medical officer of health considered it necessary, that the administration of the Vaccination Acts should be in the hands of the metropolitan borough councils, the county borough councils, and (except in London) of the county councils, which last authorities should have power to delegate their duties to sanitary authorities, that the Local Government Board should undertake the duties imposed by the Acts in the case of defaulting councils, that a minimum standard of vaccination and revaccination should be prescribed by the Local Government Board, that a form of certificate of vaccination or of revaccination, stating the number, area, and description of marks produced, should *alone* be used by medical practitioners, that calf lymph guaranteed by the Local Government Board should be supplied on demand to every registered medical practitioner, that Government stations for the preparation of vaccine should be established in the provinces, and that all officials under the Vaccination Acts should have fixity of tenure of their offices It was decided to ask the Epidemiological Society and the British Medical Association to join the society in an endeavour to obtain an interview with the President of the Local Government Board with a view to legislation being introduced in the next session of Parliament to secure such powers as those indicated in the above resolutions.—Sir Michael Foster, M P, took part in the discussion and congratulated the society upon not having spent too much time upon the conscientious objector who in some way or other would have to remain. In his opinion the success of the struggle of vaccination against small pox would depend not upon the conscientious objector but upon the improved development of the machinery of vaccination He emphasised the importance of the utmost care being taken to secure the efficiency of the operation and the goodness of the material and said that he believed the greater part of the objections to vaccination came from the careless and imperfect way in which it had been performed

West Kent Medico-Chirurgical Society —The fourth meeting of the forty seventh session of this society was held at the Royal Kent Dispensary, Greenwich road, on Feb 6th, Dr George Herschell, the President, being in the chair —After the election of four new members Mr Charles J Heath read a paper on Operative and Other Treatment of Chronic Suppuration in the Middle Ear After giving briefly the pathology of the various causes of continued suppuration treatment was considered Great stress was laid on the avoidance of syringing the ear and on the importance of drying the ear with suitable wool mops and afterwards passing the fluid remedy right through the ear and Eustachian tube to the naso-pharynx, so that it could be tasted. Under these conditions, and owing to the fact that good results depended on very frequent application of the remedy and therefore that patients must use it at home, he insisted on the use of a non poisonous fluid He used spiritus vini rectificatus and thought that if it were applied in the manner stated and pumped through to the pharynx, using the tragus as the pump, it would cure 30 per cent. of all cases Removal of ossicles and membrane when diseased did not, as a rule, stop the discharge, for generally if the bones were diseased the attic and antrum were also affected and the complete post-aural mastoid operation should be carried out. The presence of granulations and bare bone in the tympanum did not show that the antrum was diseased, cases showing these characters were often rendered healthy and the purulent discharge was entirely stopped by the treatment which he advocated. In referring to the post-aural complete operation on the mastoid, he said that the long canal of the facial nerve was incomplete in three out of ten cases operated on and could be demonstrated by using the probe before any bone was removed by operation, further, knowing the exact position of the nerve it was the surgeon's *duty* to avoid injuring it and he thought that facial paralysis consequent on the operation was almost inexcusable. The locality of the two *fenestræ* should not be curetted, though the remains of the membrane and the two larger ossicles should be removed Tight packing in the tympanum for 24 hours might destroy the hearing and that portion of the cavity should never be packed at all, he advocated the freest drainage and used a large drainage-tube through the split cartilaginous meatus and as an antiseptic application to the cavity on the completion of the operation said he could not speak too highly of the glycerine and iodoform emulsion. In sewing up the wound completely behind the ear he always made the anterior flap overlap slightly the posterior flap, as it made a better ultimate scar and prevented the ear turning outwards or becoming depressed into the enlarged meatus. His cases never had more than one large dressing put on the ear and that was at the time of the operation. On the second day after the operation the patients were practically always up and dressed. In hospital their stay was from one to three weeks. Mr Heath showed six cases, in two of which the operation had been performed on both sides In all of them the hearing was remarkably good and in most of them the hearing was as good as that of any member of the society present He called the attention of the members to the small opening through which the operation was performed.—The paper was discussed by the President, Mr J P Purvis Mr Chisholm Williams, and Mr H W Roberts —A vote of thanks was accorded to Mr Heath who briefly replied.—The next meeting, on March 6th, will be clinical

Dermatological Society of London —A meeting of this society was held on Feb 11th Mr Malcolm A Morris being in the chair —Dr J J Pringle showed a man, aged 38 years, suffering from a Syphilitic Eruption on the Flexure of the Right Knee the Face and the Lips The individual lesions consisted of deep-seated nodules which were softening in the centre The duration of the oldest portion of the eruption that on the knee, was 10 weeks and there was a history of a sore on the penis 13 weeks before The question arose as to whether this was a relapsing syphilide from a previous attack of which no history could be obtained or whether it was a precocious nodular syphilide —Dr E G Graham Little showed a case of Lichenoid Eruption, possibly Lichen Planus in an Infant. The eruption consisted of an irregular patch on the inside of the right knee and two angular patches on the right lower abdomen and left groin respectively He also showed a case of Prurigo Hebra in a woman The features of the original trouble were obscured by the immense amount of chronic eczema present and there was very little sign of the initial lesion visible at the time of exhibition —Dr H. Radcliffe Crocker showed a young woman suffering the normal. The diagnosis was confirmed by the family history 2 Three cases of Paralysis of the Ocular Muscles following Herpes Zoster Frontalis The constant pathological condition of the sensory ganglia in cases of zoster was almost conclusive of a bacterial infection. Therefore these paralyses were considered to be due to resulting toxins. The absence of the herpetic eruption in two was interesting as allowing many obscure cases of neuritis with paresis to be referred to zoster for their origin.—Dr Thomas Harris related a case of Unconsciousness which presented difficulties in diagnosis He first saw the patient, a man, aged 50 years, on Dec 4th, 1902, at 6 P M, in consultation with Dr A. V Davies of Shaw The patient was then sitting in a chair quite unconscious and could not be roused, although pricking caused some resentment. His colour was natural, as also were the respirations, and his pulse-rate was 80 per minute. When the eyelids were raised both pupils were at first minutely contracted, but about a quarter of an hour later when re-examined they were of normal size and slowly responded to light. The heart and blood vessels appeared to be healthy and the urine was normal. There was no paralysis of the ocular or facial muscles The limbs when lifted and allowed to drop fell in a flail like manner Five hours later Dr Davies was astonished to find the patient sitting up and in ordinary conversation with some friends. He said that he felt a little drowsy and as though he had lost count of things. Dr Davies stayed with him until 3 A M, during which time he persisted in talking and smoking At 3 A.M he was persuaded to lie down and he went to sleep At 6 A.M he was roused and given some nourishment. His bowels were moved at this time but there was nothing peculiar in the motion. At 10 A.M he was in much the same condition as on the previous evening, but more easily roused At 12.30 P M he was again talking and smoking He then had another motion which was very green and offensive From that time until Dec 7th he slept for a few hours at a time and then woke up for a few hours but since Dec. 7th up to the present time he had enjoyed his usual health When he had recovered he gave the following account of his illness. On Dec 3rd he was in his usual health and at 6 P M he had tea. At this meal he partook of a dish of cockles which were cooked by boiling No one else in the house partook of any cockles. At 8 30 P M he did not feel very well He was, however, able to attend a meeting and returned home and went to bed at 11 30 P M in apparently good health. At 5 30 A.M on Dec 4th he got up to go to his work. On getting out of bed he felt all right but then had a shooting pain in the right eye, followed by loss of sight of that eye. He proceeded to dress himself in a dazed sort of way and then called his son as he was accustomed to do He said that his legs at this time felt a bit queer, as though they did not belong to him. He walked downstairs The sight had now returned to the right eye and he lighted the kitchen gas. Immediately after that he felt "as though he was running his head into a corner" He walked towards his armchair and then became unconscious. At 7 10 A M his wife came downstairs, found she could not rouse him, and sent for the medical attendant Dr Davies, thinking the patient might have taken some narcotic drug as he had been subject to asthma, tried to rouse him and with assistance walked him about By this means in the course of a few hours he was roused sufficiently to be able to walk about alone He talked in a somewhat incoherent manner and like a man who was drunk. There was, however, difficulty in keeping him awake and about 3 P M he relapsed into complete stupor and remained so until Dr Harris saw him at 6 P M It appears that the patient had been subject to asthma for the last 18 years but had otherwise enjoyed good health He had never had any kind of fits and had not been subject to dizziness or headaches just previously to, or some time before, the attack. The patient was a very intelligent man and not at all a neurotic subject. His field of vision when tested after the attack was normal and the attacks of asthma appeared to have been true bronchial ones and not attacks of hysterical dyspnœa. Considering the long period—nearly 12 hours—between taking the cockles and the onset of the attack, together with the recurring attacks of stupor, whilst in the intervals he was quite awake and with a clear intellect, it did not seem probable that the shell fish were the cause That it was some form of auto intoxication arising from absorption of some toxic substance from the bowels was worthy of some consideration, but the attack appeared more probably to have been a manifestation of the *petit mal* of epilepsy The sudden onset with pain in one eye and loss of sight were very suggestive of that being the real nature of the attack Nevertheless, the absence of any previous attack which could suggest epilepsy in any form rendered the case unusual and worthy of record.

BRITISH GYNÆCOLOGICAL SOCIETY—A meeting of this society was held on Feb 12th, Dr Heywood Smith, the President, being in the chair—Dr H Macnaughton Jones read two cases of Cysts in the Inguinal Canal The first simulated a hernia and had been kept up by a truss, but became irreducible and increased in size and on operation was found to be a cyst containing blood and intimately connected with the round ligament in a patent canal of Nuck. The diagnosis in the second case also was difficult, but at an operation for salpingo-oöphorectomy and ventrofixation the round ligament was found spread out over, and intimately attached to, a cyst in an otherwise normal canal Quoting a case of double inguinal hernia, ultimately fatal, mistaken for hydrocele of the round ligament, he concluded that every doubtful swelling in the inguino-labial region in women indicated operation.—Mr F Bowreman Jessett described an operation for the removal of a dermoid cyst of the right ovary The appendix had been adherent to the tumour and was much thickened, and was removed after double ligature without turning back the peritoneum, Mr Jessett having found from experiments on the cadaver that by ligaturing the appendix in its entirety the mucous coat was completely divided just as the inner coat of a tied artery Mr Jessett also showed a Uterus removed for hæmorrhage due to a submucous fibroid, some two years after a ventrofixation for retroversion and prolapse. Chromic gut sutures had been passed through peritoneum, fascia, and muscular tissue, but at the second operation there were merely some peritoneal attachments to the abdominal parietes, from one half to one inch long, sufficient to prevent the recurrence of the retroversion, and some omental adhesions, but nothing to interfere with pregnancy had it occurred—certainly there was no such support as would have prevented recurrence in a case of complete prolapse.—After some remarks by the President, Dr L Garrett Anderson, and Dr F A. Purcell, Mr Jessett replied.—The President then delivered his Inaugural Address. He said that in 1884 after consultation with the leading gynæcologists of the day he had to draw up a plan and rules for the society and to convene the meeting at which it was constituted. Dr Robert Barnes accepted the position of honorary President and happily was still with them, and Sir J Halliday Croom, their late president, was a member of the first council elected From the first it had been felt that the exhibition of specimens and the reading of cases should take precedence of more formal papers In a comprehensive review of the work done by the society since its commencement he mentioned that 738 specimens had been shown, nearly all from operations and very few from necropsies. Of these, 243 were examples of fibroid tumours in the removal of which up to the year 1896 clamps and the serre-nœud were almost invariably employed, but since that date the prevailing method had been sub-peritoneal hysterectomy, and he congratulated the society on the share it had taken in the improved method of treating the stump Of ovarian tumours 140 had been exhibited, chiefly in the earlier years, for ovariotomy had come to be regarded as no longer an operation to be deferred till a tumour had developed to an inconvenient or dangerous size and probably only the rarer forms were now thought worthy of being brought before the society, of those shown 26 were dermoid and 19 malignant growths, while 14 were instances of twisted pedicle. While this mass of material proved the vast importance of surgical methods in the relief of the diseases of women, it must not be forgotten that medical methods afforded no "chips from the workshop" for exhibition, though in medical gynæcology so called there was no doubt much minor surgery Their past work had he believed, taught them that it was not the most anomalous cases that cast most light upon any form of disease and that each Fellow should bring forward any case that might show the advantage, or otherwise, of any special treatment, that it was well to follow up some particular subject till something definite had been obtained, and that vast fields for research remained for diligent investigation, for instance the etiology of cancer He gave the details of the society's scheme for the examination of monthly and gynæcological nurses as already published—A vote of opened. The results of treatment in chronic pancreatitis have been most encouraging, as out of 24 cases operated on only one patient died directly from operation and he had been reduced to the last stage of exhaustion before a surgical opinion was sought Of the 23 patients recovering from operation, with the exception of two who died a few months later, complete and perfect recovery ensued. The authors point out that these results contrast very markedly with the surgical treatment of cancer of the pancreas, where nearly half of the patients operated on have died directly as the result of operation and in those who have survived life has only been prolonged for a comparatively short time.

The subject of Pancreatic Cysts is very fully considered. The following classification is adopted and is probably as precise as our present knowledge permits (1) retention cysts (2) proliferation cysts (cystic adenoma and cystic epithelioma), (3) hydatid cysts, (4) congenital cystic disease (5) hæmorrhagic cysts, and (6) pseudo-cysts The authors admit that from a pathological standpoint the inclusion of the last form is not permissible As, however, the clinical features tally precisely with those of true pancreatic cysts, the academic objection rightly gives way to considerations of convenience The book concludes with a chapter on New Growths of the Pancreas

The work, as a whole, is an interesting and valuable contribution to our knowledge of pancreatic disease and the authors have been successful in carrying out the objects which they had in view

---

Methods and Theory of Physiological Histology By GUSTAV MANN, M D C M Edin., B S Oxon., Senior Demonstrator of Physiology in the University of Oxford. Oxford At the Clarendon Press 1902. Pp 488 Price 15s

THIS work is intensely practical and its value is due to the fact that the methods described are based largely upon the researches of the author assisted by his colleagues The author states that nobody realises what labour there is before the histologists and he is hopeful that the publication of his book if it fulfils no other purpose will serve to bring out deficiencies in theories and in methods. That is a very philosophic view The work is divided into eight parts. In Part I. are chapters upon the value of fixation and the chemicals used as the agents of fixation the macroscopical effects of fixing reagents the microscopical phenomenon of coagulation and precipitation and instructions as to the selection of the ' fixative This section is, perhaps, the most valuable in the work, as it is the lengthiest. Part II. contains chapters on bleaching, isolating and decalcifying, and on injecting blood and lymph vessels Methods of obtaining sections and a history of microtomes and how to use them are described in Part III. while Part IV is devoted to the nature of dyes and to the history of the methods of staining In this section a most interesting historical account of staining is given. The author rightly asks the reader to reflect occasionally on the work accomplished by older histologists without the aid of stains. The method probably commenced in the early 'fifties' and it is hardly possible to estimate how valuable an instrument dyes have been to the modern histologist and bacteriologist. A means of differentiation was thus opened up which otherwise could not have been possible. The section dealing with staining is again on account of its great importance, very exhaustive.

Passing over Part V and Part VI. the latter dealing with the chemistry of some tissue constituents and microchemical reaction we come to Part VII in which in Chapter XXIV the theory of staining is discussed and here we cannot help quoting the author's excellent views as to the objects of staining which are as follows 1. To help us in determining morphological facts. In this case all methods, no matter whether physical, chemical, or physico-chemical, are justified. 2. To recognise microchemically the existence and distribution of substances which we have been made aware of by macro-chemical means It is not sufficient to content ourselves with using acid and basic dyes and speculating on the basic or acid nature of the tissues or to apply colour radicals with oxidising and reducing properties, but we must endeavour to find staining reactions which will indicate not only the presence of certain elements, such as iron or phosphorus but the presence of organic complexes, such as the carbohydrate group, the nucleins, protamins, and others In this last sentence are summed up the spirit and substance of the work. Finally, Part VIII. contains one chapter devoted to the methods of rendering preparations permanent and an appendix follows which gives shortly the chemistry and constitution of the dyes

We most heartily congratulate the author on the accomplishment of a very big task. He could not have achieved it without a very sound acquaintance with the modern developments of physico-chemical phenomena. The materials have been collected with evident care and were largely drawn from the author's own researches. The book is full of most valuable practical instructions bearing upon histological methods and altogether this important branch of study is certain to gain considerably by this admirable attempt to elucidate principles.

A Text-Book of Obstetrics for Practitioners and Students By various authors. RICHARD C NORRIS, M.D Editor, ROBERT L DICKINSON M.D, Art Editor With nearly 900 Illustrations. Second edition, revised, Vol. I., pp. 554, Vol. II, pp 549 London and Philadelphia W B Saunders and Co. 1902 Price 35s net

SINCE the first edition of this book appeared many important advances have been made in the art of obstetrics As the editor points out, the results of bacteriological and chemico-biological researches as applied to the pathology of midwifery and the wider range of surgery in treating many of the complications of pregnancy, labour and the puerperal period embrace many new problems some of which have found their final place in obstetric practice. It has been thought proper, therefore, to issue a thorough revision of this text-book. Unfortunately since the appearance of the first edition Dr T. Parvin, Dr. J H. Etheridge, and Dr C W Earle have died. The chapters originally written by Dr Etheridge have been rewritten by Dr Clarence Webster whose name appears for the first time as one of the contributors and the editor has revised the portions written by Dr Parvin and Dr Earle. Considerable evidence of alteration and revision is present in different parts of the book. The section upon Diseases of the Ovum has been very largely added to and is now much fuller and more satisfactory than it was in the first edition. In the section upon the Diseases of the Placenta we note with satisfaction that the old heading "placentitis" has disappeared, and it is pointed out that much of the work published dealing with diseased conditions of the placenta is worthless because it was done at a time when the true nature of the placenta was not properly known. The views of Dr D Berry Hart upon the mechanism of abortion are given and a very interesting illustration of the condition known as tuberose subchorionic hæmatoma of the decidua has been added. How thoroughly the section of the book dealing with the Pathology of Pregnancy has been revised is shown by the fact that the bibliography contains some 200 additional references. A very full and interesting account is given of the condition known at the present day as the toxæmia of pregnancy and the toxic origin of eclampsia is accepted as the most likely cause of that disease. In discussing the treatment of eclampsia the principles laid down from Ulceration of the Legs, the ulcers were of about the size of sixpenny pieces and showed no infiltration of the base, being surrounded by pigmented skin There were scars of former ulcers and the patient gave the history of wandering from hospital to hospital in search of relief The diagnosis offered was that of dermatitis artefacta and this was accepted by all the members He also showed a man suffering from a Pruriginous Eruption scattered over the body and extremities The individual lesions appeared to be infiltrated follicular papules which became pustular, necrosed, and healed with scarring The patient had multiple enlargement of the lymphatic glands and the diagnosis offered was that of pseudo leukæmia also affecting the skin.—Mr Arthur Shillitoe showed a case of unusually widespread Morbilliform Erythema in early syphilis A careful inquiry had excluded any drug eruption and the rash had already persisted for some weeks

Medico Legal Society—A meeting of this society was held on Feb 10th, Sir W J Collins the President, being in the chair—The adjourned discussion upon Dr H. Littlejohn's paper on Medico Legal Post-mortem Examinations was carried on in the same friendly and animated manner as at the opening meeting The speakers upon the subject were unanimous in support of calling in a skilled pathologist, about which so much had been heard of late, and a comparison was drawn between the English and Scottish procedure in matters of investigation.—Mr F Gordon Brown, who was employed by the police at the time, read a paper upon the Whitechapel Murders. After describing in detail the terrible story of murder and mutilation he endeavoured to come to a conclusion as to the character of the murderer, it could not, he said, be due to robbery or jealousy considering the depraved natures of the victims, neither was it for the satisfaction of sexual lust, for in no case had there been violation, but he concluded that it must have been the act of an insane man with full knowledge as a slaughterer and must be classed under the term of Sadism.

Nottingham Medico-Chirurgical Society—A meeting of this society was held on Feb 4th, Mr J Mackie, the President, being in the chair Dr A. S Green (Lincoln) showed x ray photographs of (1) Spiral Fracture of Tibia, (2) Congenital Malformation of Foot, (3) Empyema of Left Chest, and (4) Impaction of Surgical Neck of Humerus—Mr W A. Howitt showed an x ray photograph of a Spiral Fracture of the First Phalanx of the Ring Finger of the Right Hand—The President, Dr W Hunter, and Dr F H. Jacob discussed the cases—Dr Jacob read a paper on Quacks and Quack Medicines which had been compiled by Mr S R. Trotman and himself Many well known patent medicines had been analysed, the greater part of the analyses being performed by Mr Trotman, and the formulæ for these were presented to the meeting—An excellent discussion followed in which the President, Mr W M Willis, Mr T Geraty, Dr C H Cattle, Dr W Hunter, Dr A Fulton, Dr Green, Mr J Thompson, and Dr Parry Jones took part, and Dr Jacob replied

Edinburgh Royal Medical Society—A meeting of this society was held on Feb 13th. Dr A. B Ross, senior President, being in the chair—Mr R M Johnstone communicated notes on a case of Myositis Ossificans The patient was a man, aged 35 years who was shown before the society The condition began when he was eight years old and had become gradually worse with acute exacerbation at varying intervals. During the acute stage the muscles were swollen and very painful and after the symptoms had passed off ossification set in. Many of the joints were ankylosed The muscles of the abdomen were not affected at all—Dr W M McFarlan read a paper on Abdominal Pain

Wigan Medical Society—The annual meeting of this society was held on Feb 12th, Mr T M Angior, the President, being in the chair There was a good attendance of members present. After the election of office bearers a social evening was agreeably spent. The following gentlemen were elected office bearers for 1903—President Dr Matthew Benson. Committee Dr Benson (President), Mr T M Angior (ex President) Mr W Mitchell Roocroft, Dr R. P White, Mr C M Brady, Dr John Blair, Dr Ferdinand Rees, Dr George Wolstenholme, and Mr Winstanley Treasurer Mr E. H. Monks, J P Honorary secretary Mr William Berry

Reviews and Notices of Books.

Diseases of the Pancreas and their Surgical Treatment By A W MAYO ROBSON, F R C S Eng, Senior Surgeon, Leeds General Infirmary, Emeritus Professor of Surgery, Yorkshire College, Victoria University, and B G A. MOYNIHAN, M S Lond, F R.C S Eng, Assistant Surgeon, Leeds General Infirmary, Consulting Surgeon to the Skipton Hospital and to the Mirfield Memorial Hospital Illustrated London and Philadelphia W B. Saunders and Co 1902 Pp 293. Price 12s

IT is only within recent years that any material progress has been made in regard to our knowledge of the functions and diseases of the pancreas The experience gained by pathologists, however, demonstrates that this organ not infrequently proves a source of serious, and often fatal, disease. The authors of the work now under consideration state that they have had a twofold object in the publication of a book dealing with the surgical aspects of pancreatic disease—namely, to record and to review the investigations accomplished in the past and to indicate, as far as is possible, the scope and trend of future research

The first chapter deals with the Anatomy of the Pancreas. Due credit is given to the admirable works of Körte and Oser, and the results of the inquiries of Opie and others into the functions and significance of the islands of Langerhans Chapter II. deals with the conclusions arrived at by the many observers who have conducted experimental researches on the organ, more especially in regard to the artificial production of diabetes It has been clearly shown that total extirpation of the pancreas produces all the symptoms of diabetes. Glycosuria, however, does not appear when any portion of the gland—head, body, or tail—is left, but at once manifests itself if the remnant be subsequently removed. Very interesting are the remarks on Pancreatic Diabetes in Man. The authors conclude that in a large number of cases diabetes is associated with or accompanied by, disease of the pancreas, the most frequent of which is a chronic interstitial inflammation and sclerosis. On the other hand, however, cases of diabetes occur in which there is no demonstrable affection of the pancreas and cases of chronic interstitial inflammation are seen without the phenomena of diabetes The valuable researches of Opie are again referred to From pathological observations this authority maintains that the destruction of the islands of Langerhans is concerned in the production of diabetes and this view is maintained by the experimental work above alluded to

The condition of Inflammation of the Pancreas is fully considered, four chapters being devoted to this subject The authors' classification of pancreatitis differs from that adopted by some other authorities. Mr Mayo Robson and Mr Moynihan are of opinion that it is convenient to consider pancreatitis clinically under the headings of (1) acute, (2) subacute, and (3) chronic, which does not interfere with Fitz's pathological classification of acute pancreatitis into hæmorrhagic, suppurative, and gangrenous We agree with the authors that for clinical purposes the plan they have decided upon is quite satisfactory The symptoms, diagnosis, and treatment of these forms of pancreatitis are well described although some of the cases recorded might have perhaps been given more succinctly The remarks on the treatment of chronic pancreatitis are especially worthy of note The authors maintain that cases of this nature must be treated by abdominal section and drainage, but the drainage should be indirect and obtained by draining the gall bladder by cholecystotomy or cholecystenterostomy or the pancreatic and common bile duct together by duodeno choledochotomy, the exact line of treatment cannot be determined until the abdomen is title indicates, the book is intended more particularly as a guide to medico-legal work in India. Many subjects, therefore, are discussed which are not to be found in the purely English manuals, as the law of India is different from that of England in certain matters which come under the notice of the medical jurist. For instance, Chapter VI, which deals with the subject of Age, contains details of the Indian Penal Code in relation to certain acts which are not otherwise offences, but become offences when done to persons below certain ages which are specified. There is also a material difference as to the age of "consent" in trials for rape according to the English and Indian laws

The chapter on Infanticide will be found interesting In most countries infanticide is resorted to in order to get rid of the offspring of illegitimate intercourse or of the legitimate children of parents too poor to support an additional tax on their resources. In India, however, there are reasons specially referable to the social conditions that exist amongst certain races which account for the destruction at birth of children and more particularly of female children. These reasons are fully discussed and disclose conditions which happily are gradually disappearing under British rule.

The section on toxicology however, in our opinion forms the most instructive portion of this volume. Much that is contained in this part of the work is beyond the requirements of the student for examination purposes but forms valuable material for reference. Many poisonous substances are dealt with and in the chapters devoted to vegetable poisons plants are mentioned which are peculiar to tropical countries and several excellent plates are introduced representing the appearance of some of the plants. The methods employed for detecting the poisons are clearly given and the medico-legal points which may arise are fully discussed We can cordially recommend this volume to those readers for whom it is intended

LIBRARY TABLE.

Spirals in Nature and Art. By THEODORE ANDREA COOK M.A. F S A., with a preface by Professor E. RAY LANKESTER, F R.S London John Murray 1903 Pp 200 Price 7*s* 6*d* —Some time ago Mr. W Lethaby wrote a most interesting book entitled 'Architecture, Mysticism, and Myth,' in which he pointed out how architectural forms and decorations were derived from the study of natural objects or developed with a view to symbolise natural phenomena. Mr Cook has taken a portion of the same very wide subject for his charmingly written essay He discourses upon spirals and draws attention to the fact that the exquisite spiral staircase in the Chateau of Blois was evidently modelled upon the form of a shell—namely *Voluta vespertilio* and that upon the rare reversed variety the spiral being left-handed. Mr Cook is of opinion that the architect of this wonderful staircase was Leonardo da Vinci. That great man, of course, lived for some time in the Loire valley and was buried at Amboise. He was certainly capable of building the staircase in question and as Mr Cook proves from the drawings which he left behind him Leonardo da Vinci took great interest in spirals He was also left handed, which would account, thinks Mr Cook for the staircase having a left-handed spiral. Whether Mr Cook be right or not about Leonardo da Vinci does not very much matter but we think that he certainly makes out a very strong argument for the staircase having been modelled from the shell. Many other examples of spirals and spiral growth in animals and plants are given but there is a screw formation which Mr Cook does not refer to, and although perhaps it comes under the heading of neither nature nor art we may call attention to it. We mean that obtained by dipping a helix of wire with a central supporting column into soap film The beauty of the resulting surface is very remarkable. Architects will find Mr Cook's little book very interesting

"The Green Republic" a Visit to South Tyrone By A. P A. O'GARA, M.D London T. Fisher Unwin. 1902. Pp 244 Price 6*s* —Any light thrown on the Irish agrarian and land question should be welcomed, but it is to be feared that Dr O'Gara's book, which deals exclusively with this subject, will not, to any appreciable extent, enlighten the darkness which enshrouds this complex subject. Dr O'Gara's views are set forth in the preface, introduction, and conclusion of the work, the rest consists of 12 sketches, or rather dialogues, which merely serve to elaborate and to illustrate his arguments in the form of somewhat wordy and diffuse discussions on the various points. Dr. O'Gara takes an extraordinarily pessimistic view of the Irish land problem and has a very poor opinion of Irish tenants as a class. He appears to be convinced that any hope of Irish tenants working out their own salvation (and incidentally that of their country) by eventually becoming the owners of their own land is quite futile—a view, by the way, diametrically opposed to that of the recent land conference held at Dublin between representatives of the landlords and of the tenants. Dr. O'Gara advocates as a panacea for the evil the working of the land by joint-stock companies run on strictly business lines—a suggestion quite outside the domain of practical politics. To earnest students of the Irish land problem this book will be of much interest.

JOURNALS AND MAGAZINES

Journal of Anatomy and Physiology Conducted by Sir WILLIAM TURNER K.C B, F R S., D J CUNNINGHAM, M D, F R.S., G S HUNTINGTON M.D, A. MACALISTER, M.D., F R.S, and J G M'KENDRICK, M D, F R.S Vol. XXXVII. Part 2 January 1903. With Plates and Figures in the Text. London Charles Griffin and Co, Limited. 8vo. Price 6*s* —The contents of this number are as follows 1. Johnson Symington M.D Edin, of Belfast Are the Cranial Contents displaced and the Brain damaged by Freezing the Entire Head? (with a plate.) The author comes to the conclusion in opposition to Professor Froriep that no alteration in these respects is effected by freezing 2. R. Broom, M.D Glasg on the Development of the *Pterygo-quadrate* Arch in the Lacertilia. In this article the author demonstrates the occurrence of a cartilaginous connexion between the quadrate and epipterygoid in various and very diverse lacertilian embryos rendering it practically certain that the immediate ancestors of the lizards were possessed of a fixed quadrate as in sphenodon a point of considerable importance in classification. 3. O Charnock Bradley, M.B. Edin., professor of anatomy Royal Veterinary College, Edinburgh on the Development and Homology of the Mammalian Cerebellar Fissures, Part 1, with five plates. This article describes the formation of fissures in the cerebellum of rodents. 4 H. W Marett Tims, B A. Cantab M D Edin. the Evolution of the Teeth in Mammalia 5 J O Wakelin Barratt M.D Lond., the Form of the Dilated Cerebral Ventricles in Chronic Brain Atrophy, with numerous woodcuts. 6. Walter H. Gaskell, F R.S., on the Origin of Vertebrates deduced from the Study of Ammocœtes, Part III This part deals with the origin of the vertebrate body cavity and excretory organs and is an attempt to explain the meaning of the somites of the trunk and of the ductless glands. Dr. Gaskell endeavours to show in these interesting papers that the ancestor of the vertebrates was not an arachnid purely or a crustacean purely but possessed partly crustacean and partly arachnid characters 7 The Proceedings of the Anatomical Society of are that the convulsions should be controlled, elimination stimulated, and the uterus emptied. The administration of chloroform and oxygen is recommended but ether should be used for any prolonged operative measure. The author of the section, Dr Davis recommends the avoidance of pilocarpine, the administration of large doses of morphia, the practice of venesection, profound and prolonged anæsthesia, and rapid emptying of the uterus when no sign of spontaneous labour is present When the circumstances are favourable, however, and the cervix cannot readily be opened Cæsarean section may be performed. No doubt in future editions, if rapid emptying of the uterus be still advocated, the employment of Bossi's dilator will take the place of Cæsarean section in such cases There is much more new matter that has been added to many of the other sections but we must refer our readers to the book itself It is a most valuable work and will prove of service not only to students and practitioners but also to teachers of the science and art of obstetrics A number of new illustrations have been added and some of the old have been re-drawn. The book is now published in two volumes, each with separate paging and index. There is also a general index which is not so full as might be wished in such an important text book.

Madrid bajo el Punto de Vista Médico social Por el Dr PH HAUSER, &c Dos partes Madrid. 1902. 8vo, pp 919 Price 25 pesetas. (*Madrid from the Medico social Point of View* By Dr PH. HAUSER, &c Two volumes Madrid. 1902 Price about 14s 6*d*)

DR. HAUSER has undertaken the gigantic task of pointing out in detail the sanitary defects of Madrid as compared with other great cities, and in so doing he has not spared the country of his adoption. He has taken great pains in the years during which he has resided in Madrid to ascertain thoroughly the sanitary condition of the town, and in his endeavours he has been rather thwarted than aided by the authorities. It is satisfactory to learn from the preface to the second volume that his book has been well received by the medical profession in Spain, and it is to be hoped that its members will use what authority they have in procuring a reform of the many faults which he points out

The book begins with the history of the evolution of sanitation in Madrid from its foundation to the present time, with a complete topographical and geological description of the city, its soil, and the effect of the soil upon its climate and hygiene. Dr Hauser devotes a whole chapter to an account of the different methods of purification of sewage and of the prevention of contamination of the soil—a chapter very necessary in Spain where even the most elementary knowledge of hygiene is lacking He then proceeds to describe very accurately the system of sewerage in Madrid, pointing out the course and the defects of the existing sewers He states that 431 streets are entirely destitute of sewers, that 93 streets are but partially drained, and that in the 586 streets which are supposed to be properly sewered there are hardly *100 houses* (*sic*) which are really in a thoroughly sanitary condition. The author next describes the different varieties of material used on the roads and the methods adopted in cleansing the roads, comparing these with those employed in Paris and in Berlin Next we are informed about the sources and state of the drinking water which is not filtered and contains, besides other impurities, from 1650 to 2860 bacteria per cubic centimetre and is at times offensive to sight and smell. Fortunately the wines are good and cheap and *chufa* makes an excellent summer drink if the drinker can only be sure that the water with which this root of the *Cyperus esculentus* is mixed has been boiled. Dr Hauser passes next to the workmen's quarters in Madrid, these are wretched barracks with no water supply, no ventilation, very little light, and no attempt at drainage in the houses or streets These quarters are naturally nests of infectious diseases. There are in Madrid town 438 houses which harbour 52,655 persons, or an average of 110 inhabitants per house, the actual numbers varying between 107 and 152 per house. Dr. Hauser, after describing the attempts made in England, France, Germany, and Belgium to improve artisans' dwellings, mentions some private societies founded in Madrid with this object. He next treats of the slaughter houses, markets, and butchers' shops in Madrid and their deficiencies. After this comes a critical description of the hospitals in Madrid. The author also criticises the theatres, schools, churches, barracks, and public houses in Madrid, and concludes his first volume with the demography of the town, discussing the density of population, the birth rate, the mortality, and the number of marriages during a series of years. He gives a large coloured plan of the town showing the rate of mortality in the various districts

As the first part of this work treated of social hygiene, so the second part, which appeared in December, 1902, treats of medicine from the public health point of view and begins with a general dissertation on the etiology of infectious diseases, proceeding to a description of the mortality from the different varieties of infectious disease, the author expressing a decided opinion that it is the soil of Madrid, not the water or the air, which is the cause of the prevalence of infectious deisases there. From the tables given it would appear that tuberculosis, small pox, and measles are the most fatal diseases in Madrid, typhoid fever, scarlet fever, and puerperal fever have a much smaller death rate than the first-named maladies Dr Hauser doubts whether mosquitoes are the cause of paludism. Syphilis and other venereal diseases are discussed at length, the conclusion arrived at being that police regulation of prostitution is ineffectual for the prevention of venereal disease, which is certainly true in Spain where the regulations are lax and are constantly evaded.

A whole chapter is devoted to the causes of the mortality among the lower orders in Madrid and another to the connexion between the frequency of disease and meteorological conditions The book ends with an account of the sanitary measures which have been adopted by the police in various epidemics In an appendix by Dr Montaldo there is a comparative analysis of the sanitary legislation of France, Italy, Portugal, and Spain.

The book is of necessity large and cumbrous, because the author has been obliged to describe minutely even the simplest sanitary matters which are new to his readers though familiar to us from long experience It is impossible in the limited space of a review to do justice to the amount of care and pains which Dr Hauser has expended on this work or to the excellence of the results in spite of the difficulties which he met with

---

Legal Medicine (in India) and Toxicology In two volumes. By Major COLLIS BARRY, I M.S , F R.S Edin., Chemical Analyser to the Government of Bombay , Professor of Chemistry, Medical Jurisprudence and Toxicology, Grant Medical College, Bombay Illustrated by Plates. Vol. I. Bombay Thacker and Co , Limited Pp 685

THIS work was originally undertaken to supply a text-book for the students of the Indian colleges. The author states in his preface that the mass of material collected for the book is so large that it was deemed advisable to transfer the greater number of the illustrative cases to a separate volume As a manual of jurisprudence this publication is certainly deserving of praise. The various subjects are judiciously dealt with , the method of arrangement of the chapters into paragraphs by means of heavy type is useful both for purposes of study and reference , and we believe that students will find the work a trustworthy text-book when preparing for their examinations As the secondary products upon which, according to our view, the question of whether or not the spirit is genuine brandy can be decided the following were the results recorded in grammes per hectolitre of alcohol (100°) acidity, calculated as acetic acid, 82 08 grammes, aldehydes, 14 24 grammes, furfural, 1 36 grammes, ethers, expressed as ethyl acetate, 90 28 grammes, and higher alcohols, 129 96 grammes We have no doubt that this brandy is genuine grape spirit and of a good class, and it is stated that it is a blend of various shipments by well known Cognac growers. The amount of extractives is somewhat high, while the colour is dark rather than pale The sample possessed the pleasing flavour and aroma of mature Cognac brandy

(1) INVALID PORT AND (2) PORT MATURED IN NEWFOUNDLAND

(Hunt Roope Teage and Co 3 and 4 Water lane, Great Tower-street London E C)

1. On analysis the invalid port gave the following results total extractives, 8 34 per cent., mineral matter, 0 18 per cent, alcohol, by weight 18 85 per cent., by volume 23 10 per cent, equal to proof spirit 40 48 per cent., volatile acidity, calculated as acetic acid, 0 072 per cent., fixed acids, calculated as tartaric acid, 0 21 per cent, and sugar, 7 10 per cent This is a good full fruity wine soft to the taste and dark in colour, it is said to be produced in the best district of the Alto Douro An interesting point in regard to the analysis is that we found distinct traces of manganese in the mineral matter The wine is mature yet full bodied and suitable as a restorative in special cases. 2 This wine is of the "tawny" type. Analysis gave the following results extractives, 8 07 per cent., mineral matter 0 22 per cent, alcohol, by weight 18 08 per cent, by volume 22 18 per cent. equal to proof spirit, 38 87 per cent., volatile acid, *nil*, fixed acids, calculated as tartaric acid, 0 15 per cent., and sugar, 7 10 per cent. This is practically a non acid wine It is said to have been matured in Newfoundland. It possesses excellent æsthetic qualities Both specimens are good sound wines and suitable for invalid use.

PENFOLD'S AUSTRALIAN WINES

(J G Thomson and Co 17 Fenchurch street London E.C)

These specimens are interesting in proving that Australian wines imported into this country need not necessarily be of a heavy character The following are the results of the analysis of a specimen of claret and of a specimen of chablis. Claret No 0 extractives, 2 63 per cent., mineral matter, 0 28 per cent, alcohol, by weight 11 15 per cent, by volume 13 81 per cent., equal to proof spirit 24 19 per cent., volatile acids, calculated as acetic acid, 0 096 per cent., fixed acids, calculated as tartaric acid, 0 23 per cent., and sugar, 0 43 per cent. Chablis No 1 extractives, 1 86 per cent., mineral matter 0 2 per cent., alcohol by weight 11 08 per cent., by volume 13 71 per cent., equal to proof spirit 24 03 per cent., volatile acids, calculated as acetic acid, 0 12 per cent, fixed acids, calculated as tartaric acid, 0 35 per cent., and sugar, 0 57 per cent. Both are sound, light, agreeable wines.

CHAD VALLEY PINE PAPER

(Johnson Brothers Chad Valley Works Harborne, near Birmingham)

We have examined specimens of this paper and amongst other things found that ether extracts a resinous oil possessing a smell of fresh sawdust. The addition of this oil is regarded as a sanitary precaution.

BARDELLA BANDAGE.

(Agents: Down Bros 21 St Thomas's-street London S.E.)

The bardella bandage consists of a roll of lint loaded heavily with a mineral powder which, according to our examination, contained chiefly bismuth and zinc. The bandage is well spoken of as an application for burns scalds, and injuries. It certainly has a soothing and healing effect upon burns. The bandage admits, of course, of a number of useful applications.

STERILISING SOAP

(F S Cleaver and Sons 32, 33 34 Red Lion-street Holborn London, W C)

This soap is excellent in use, lathers well, and contains no free alkali In the course of its preparation a volatile antiseptic substance is added owing to which, we assume, the soap is regarded "as a preventative against bubonic plague and malaria." Of course, the free use of soap is always calculated to preserve the cleanliness of the person and the conjoint use of an antiseptic with it is no doubt an advantage in some circumstances. But it is an exaggeration to say that this soap would prevent bubonic plague and malaria.

New Inventions.

A SERVIETTE CASE FOR OPEN AIR SANATORIUMS

Everyone who has experience of sanatorium life is familiar with the table napkin question At many open air institutions the patients are provided with Japanese paper serviettes, but nine out of ten patients object to the sensation of applying the paper napkin to their mouths and the tenth does not like its smell, and nearly all would rather be deprived of serviettes altogether than be dependent upon the paper variety There are objections to the use of the linen napkin in that being used for more than one meal and packed away in a drawer in the interval with only the protection of the napkin ring an undesirable contact between the serviettes of different patients is unavoidable The phthisical patient who not only uses his table napkin in the ordinary manner but instinctively raises it to his mouth when obliged to cough at table cannot fail to infect it with tuberculous bacilli, and since the aim of every sanatorium superintendent must be to achieve the most perfect possible condition of hygiene in his institution he cannot afford to risk infection by serviette. To meet the difficulty which ensued when I had to admit that the paper napkin and the uninclosed linen serviette were unsatisfactory I devised a serviette cylinder made of solid celluloid with smooth surfaces which is easily cleansed and which entirely envelopes the napkin, thus protecting it from all contact with others These cylinders are not unattractive in appearance and they are so much appreciated by patients that many ask to be allowed to take one away when leaving the sanatorium. It would be a decided advantage to visitors at boarding houses, where, unfortunately, so many tuberculous patients are wont to congregate, were some such arrangement adopted to prevent infection by means of tuberculous table napkins, and in families where some member is phthisical the use of the cylinder would be equally advantageous. At my suggestion Messrs. Allen and Hanbury have made a supply of serviette cylinders an illustration of which is reproduced here. They are quite inexpensive.

Chelsea, S W

A NEW FORM OF FINSEN LAMP

This lamp is designed to meet the demand for a very small lamp automatic in its action, burning iron or carbon electrodes and working direct from the electric supply main These conditions are fulfilled by making the shell of the lamp a water jacket of very small proportions, mounted on a frame which permits motion in all directions and at the same time is rigid when in working position. It is imperative that the diseased area to which the lamp is applied should be rendered anæmic, so that the rays can penetrate

Great Britain and Ireland which contain amongst other articles a particularly valuable one by Arthur Keith, M D Aberd , on the Heart

The Phonographic Record of Clinical Teaching and Medical Science February, 1903 Issued by the Society of Medical Phonographers. London Sir I Pitman and Sons, Limited. Pp 16 Price 6*d* —This number contains an account of three cases of stab wound of the liver in a Chinese and two Malays recorded by Mr R. M Connolly, district surgeon, Batu Gajah, Perak Mr Connolly says that in a country such as this, in which tropical abscess is not uncommon, it may be thought that the surgery of the liver is limited solely to the opening of tropical abscess of that organ, but that a short residence in a district where highway robbers walk the roads would be sufficient to dispel the delusion There are also some notes of clinical teaching by Sir William R Gowers which were taken some years ago on the case of a man, aged 65 years, who suffered from paralysis agitans and senile cerebral degeneration. Sir William Gowers says that it is probable that paralysis agitans consists of a degeneration of the nerve elements of the motor cortex, but that it is an internal change too slight to be expressed by structural decay He adds that only a minority of the cases correspond to the types described in text-books. Dr J C M Given gives particulars of the case of a man, aged 65 years, whom he has had under observation for the last ten years. He had an attack of kidney trouble 30 years ago, and Dr Given has attended him for four attacks The urine contained blood cells, albumin, and casts, both granular and epithelial. He kept to practically a white meat diet and for several months was a pure vegetarian with the exception of milk, but the albumin never disappeared. For the last two years he has been attacked with a severe form of rheumatoid arthritis and on this account he has been allowed a much more liberal diet with plenty of red meat, and now a curious thing is that he has been almost completely free from albumin His general health is now good apart from the crippled state of his joints The secretary of the society reports that the number of members is now 184 against 203 at the commencement of the year, and that another examination will be held this year, in May, although the finances of the society are not sufficiently good to be able to give two £5 prizes, it has been decided to offer two £3 prizes Those thinking of presenting themselves for the examination should write to Dr P G Griffith, Bonhams, Farnborough, Hants There also appears to be some difficulty in collecting the subscriptions, judging from an appeal which is printed in the *Record*

The Practitioner —The February issue of the *Practitioner* contains much weighty food for thought Whether the reader has a medical, a surgical, or a purely speculative bias, he will find something to his taste either in the eloquent writing of Professor T Clifford Allbutt, the deep chemistry of Dr Walter G Smith of Dublin, or the practical suggestion of Mr A W Mayo Robson. A short article by Dr E W Ainley Walker sums up well the present claims of the micrococcus of rheumatism to be admitted as a "specific" agent and points the direction for further investigations. The endless interest and obscurity of the origin of eclampsia in the pregnant woman are treated by Dr W E. Fothergill and articles are contributed by Mr Stephen Paget, Mr Harold L Barnard, and Mr E Treacher Collins amongst others

---

HEALTH OF CLEVEDON —Mr W J Hill, the medical officer of health, at the meeting of the Clevedon (Somerset) urban district council held on Feb 4th presented his annual report for 1902. The population of the town was 5896, the birth rate was 18 3 per 1000, and the death rate was 12 9 per 1000

Analytical Records

FROM

THE LANCET LABORATORY.

' MARMITE FOOD EXTRACT

(THE MARMITE FOOD EXTRACT CO LIMITED 40, MINCING-LANE LONDON, E C)

MARMITE extract is prepared from the yeast cell which, as is well known, contains important food constituents The extract is hardly distinguishable as regards appearance, taste, and smell from ordinary extract of meat, while our analysis shows that it has a similar composition. The results were as follows moisture, 28 80 per cent , albumins, 1 10 per cent. , peptone, 4 76 per cent. , albumose, 9 92 per cent , nitrogenous basis, 20 63 per cent. , mineral matter, 25 42 per cent , and non nitrogenous matter by difference, 9 37 per cent The total nitrogen amounted to 5 78 per cent In this analysis attention may be called to the peptone albumose, and the mineral matter, the last being rich in phosphatic salts. This entirely vegetable extract possesses according to these results the same nutrient value as a well prepared meat extract.

GRANALT" PREPARATIONS

(THOMAS CHRISTY AND CO 4 10 AND 12, OLD SWAN LANE UPPER THAMES-STREET LONDON, E C)

As its name implies "granalt" consists of dry granulated malt extract. It is a crisp powder with a pleasant malty taste but exhibits no diastatic action on starch, according to our experiments The preparation of course contains the soluble constituents of malt. Granalt appears to be an excellent vehicle for cascara sagrada, the glycero-phosphates, and even castor oil

THROGMORTON WHISKY

(J LYONS AND CO , CADBY HALL, KENSINGTON LONDON W)

Our analysis of this whisky corresponds very closely with that of a Scotch whisky (known to be all malt and eight years old) which was quoted in the report of THE LANCET Special Analytical Commission on Brandy published in THE LANCET of Nov 29th, 1902, p 1503. Thus the figures in regard to the secondary products were as follows, given in grammes per hectolitre of alcohol (100°) volatile acids, calculated as acetic acid, 42 08 grammes , fixed acids, calculated as tartaric acid, 19 00 grammes , aldehydes, 26 30 grammes , furfural, 4 25 grammes , ethers (ethyl acetate), 72 19 grammes , higher alcohols, 212 80 grammes These results are in perfect accord with the statement that the whisky is an all malt spirit and without the addition of grain spirit, moreover the results indicate age. Further results of analysis were as follows extractives, 0 11 per cent , mineral matter, 0 02 per cent. , absolute alcohol, by weight 40 15 per cent., by volume 47 51 per cent., equal to proof spirit, 83 26 per cent. The whisky thus contains a minimum of extractives and saccharine matters and is pale in colour and although an all malt spirit is delicate in flavour The presence of fixed acids and a notable proportion of ethers indicate storage in a sherry cask

COGNAC BRANDY

(BROWN AND PANK, 16, MARK LANE, LONDON, E C)

On submitting this specimen of brandy to analysis the following were the results extractive matters, 1 08 per cent., mineral matter, *nil* , and alcohol, by weight 50 39 per cent., by volume 58 23 per cent., equal to proof spirit 102 05 per cent. The samples were taken directly from bond and therefore the alcoholic strength shown is about 10 per cent in excess of the usual strength of brandy on the market. In other words, this is the analysis of the brandy before it has been "broken down" As regards

LONDON SATURDAY, FEBRUARY 21, 1903

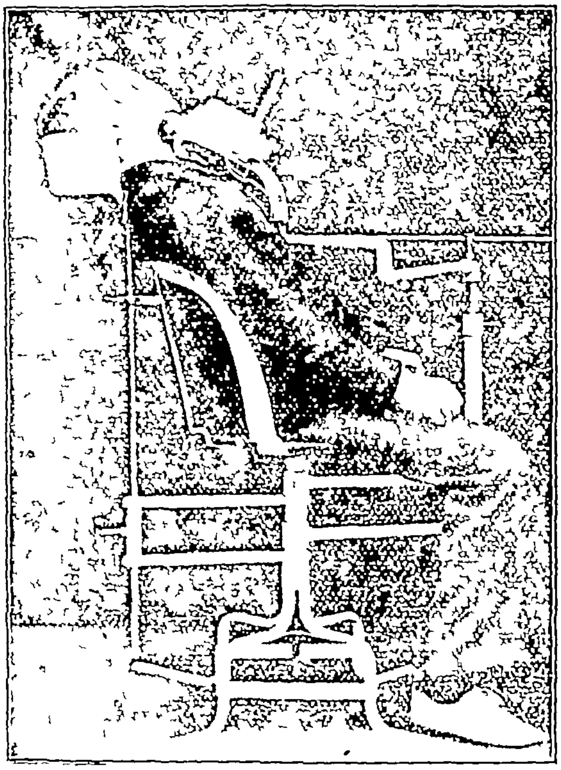
The Hunterian Oration of the Royal College of Surgeons of England

THE Biennial Hunterian Oration was delivered on Feb 14th by Sir HENRY G HOWSE, the President of the Royal College of Surgeons of England, in the theatre of the College This oration was founded in 1813 by Dr BAILLIE, JOHN HUNTER'S nephew, and Sir EVERARD HOME, his brother in law and was intended to perpetuate the memory of JOHN HUNTER by the delivery on Feb. 14th in every second year of an oration dealing with his work and the labours of others in the field of natural science and its relation to the healing art Feb 14th (St. Valentine's Day) was chosen for the occasion because HUNTER celebrated that day as his birthday, though the register of the parish where he was born gives Feb 13th as the day of his birth. With such great latitude in the choice of a subject many Hunterian orators have very variously interpreted their functions and as a result the orations have varied greatly This year Sir HENRY HOWSE spoke chiefly of HUNTER'S life and work with which many of our readers may be familiar but his career offers such an excellent example of brilliant genius supported by indomitable industry that it will bear recurring recital.

JOHN HUNTER was the youngest child of a small Lanarkshire farmer, and as his father died when the boy was only ten years old he was allowed to run wild and his education was grievously neglected. To this absence of parental control the orator attributed much of the passionate nature which HUNTER displayed in his later life. There is probably some truth in this view, but there is another aspect also from which we may regard the free, open, and unconventional life led by the boy till his twentieth year It is certain that while he ran wild on the farm he was acquiring that love of the study of the ways of beasts and birds which was so strikingly manifested later, he was gaining the habit of close and accurate observation of nature which is seldom learnt or fostered within the four walls of a school. When about 20 years old he came to London and was allowed to assist his brother WILLIAM HUNTER, his talent for dissection soon showed itself and his progress was rapid He might have become a dry as dust professor but circumstances again conspired to broaden his views, to vary his experiences, and to render his work unconventional and progressive He was appointed to the Belleisle expedition as an army surgeon and served also in Portugal, and in this way obtained opportunities for many new observations. After his return to London his original bent had full opportunity to display itself. His powers of investigation were exceedingly great, his mind well stored with facts was quick to perceive unexpected relations between facts, while theories were ever ready to spring up to explain the correlation between two phenomena, for he had an enormous range of accurate knowledge upon which to frame them As a collector he was remarkable. Though he was primarily an anatomist and a surgeon he collected not merely anatomical and pathological specimens, but also those illustrating zoology, botany, geology, and mineralogy He was willing to enlist the aid of his friends in his observations, but in investigations thus undertaken by different observers it is not surprising that differences of opinion as to priority in discovery should arise and of such disputes he had more than most men. He quarrelled at one time or another with many of those with whom he had to do and even with his brother WILLIAM. Both the HUNTERS were keen controversialists and neither could brook contradiction. WILLIAM HUNTER is said to have explained this by saying that all anatomists were impatient of contradiction because they were accustomed to the passive submission of the dead body

We hear much of HUNTER'S lack of skill in teaching, we are told by Sir HENRY HOWSE, and others have said the same, that his style was involved and that his phrases were obscure. His books, indeed, do not excel in clearness of diction, but the lucidity of his writings must not be the test of his power of teaching By his fruits must a teacher be known. Men do not gather grapes of thorns, nor can successful pupils result from bad teaching It may with confidence be affirmed that rarely, if ever, have so many brilliant men been the pupils of one surgeon. The majority of the great surgeons in London for some years after his death had been the pupils of JOHN HUNTER. ABERNETHY ASTLEY COOPER, CARLISLE, LYNN, EVERARD HOME, and BLIZARD may be mentioned as examples. On the substance of lectures rather than on the presence of flowery periods depends their success and if the hearers learn what the lecturer would teach them the exact words employed are only a matter of secondary importance And what HUNTER'S pupils learned may be summed up by saying that he laid a foundation of physiology as the basis of pathology and so furnished a true guide to treatment. Modern surgery dates from JOHN HUNTER. The importance of his museum was recognised by HUNTER, to it he devoted many years and much money almost exhausting his pecuniary resources In his will he left directions that the museum should be offered for sale to the Government The British Government can never be accused of over-estimating the claims of science on the national purse—and this is equally true of both political parties, but occasionally it happens that it does support a valuable project, and after years of hesitation the Government purchased the museum. No small credit, too is due to the then Corporation of Surgeons, the Royal College of Surgeons of England, consenting to undertake the custody of this invaluable collection.

The founders of the Hunterian Oration recognised that mental food was not the only nutriment needed by man. So when they founded the Oration they founded at the same time a biennial Hunterian Dinner to which the President of the Royal College of Surgeons of England invites eminent members of the medical and other professions. At the dinner which followed the late oration Earl ROBERTS the tissues," merely application of the lamp being futile unless sufficient pressure be exercised to produce this effect. For this purpose I obtained the chair upon which the patient is seated from Berlin and had the lamp attached to it by means of a powerful bracket, steady pressure of the lens against the patient being maintained by a rack and pinion adjustment and counter pressure by the head rest. From 15 to 20 minutes are sufficient to produce a good reaction. It is noiseless On the score of economy this lamp is a distinct advance on all modifications of Finsen's apparatus. The current is two ampères at a pressure of 40 volts across the arc The rubber water tube connexions have been removed so as not to obscure the lamp I am indebted to Messrs. John Hunter and Co of Liverpool for their skill in carrying out my suggestions. The illustration shows the lamp applied under the chin. This is one of the most difficult positions to reach, but it can be easily treated with this lamp



The lamp at work

Liverpool G G STOPFORD TAYLOR, M.D Durh

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND

A GENERAL meeting of the Medico-Pyschological Association of Great Britain and Ireland took place at the County Asylum at Mickleover, near Derby, on Feb 12th. There was a large attendance of members from all parts of the United Kingdom

The proceedings commenced in the forenoon with meetings of the council and various committees At 1 30 P M Dr R J Legge, medical superintendent of Mickleover Asylum entertained the company at luncheon. Replying to the toast of his health, which was proposed by Dr. J WIGLESWORTH, Dr LEGGE said that he was greatly obliged to the visiting committee for the readiness with which it had consented to the meeting of the association being held at Mickleover Asylum Colonel GASCOIGNE, the chairman of the asylum committee, whose health was proposed by Dr T OUTTERSON WOOD, said that his committee regarded it not only as a pleasure but as a duty to give every assistance in its power to an association the objects of which were so beneficent as its were.

The general meeting commenced at 3 P M under the presidency of Dr WIGLESWORTH, medical superintendent of the county asylum at Rainhill, Liverpool. The first business was the election of ten new members.

The PRESIDENT then said that there was a motion on the agenda paper in the name of Mr F J Stuart concerning the work of the tuberculosis committee of the association. It would be within the recollection of all present, he remarked, that that committee presented a report which was adopted, but the accuracy of the statistics which it contained was afterwards challenged and the secretary of the committee thereupon wrote to the *British Medical Journal* accepting personal responsibility for them. This, the President thought, was unfortunate, because every member of that committee was equally responsible for what the report contained The council had gone fully into the matter at its meeting that morning , the facts were being examined by an expert whose report, when it appeared, would be presented to the association and all the circumstances would be considered very fully

Mr STUART then moved —

> That a committee be appointed to reconsider and to report on the statistics obtained by the late tuberculosis committee of this association

He proceeded to criticise the statistics, asserting that they exemplified every fault both of omission and of commission that the mind of the most ingenious statistician could devise.

Dr A. S L. NEWINGTON moved as an amendment that the matter should be for the present left in the hands of the committee.

Dr DAVID YELLOWLEES, in seconding the amendment, acknowledged that they were indebted to Mr Stuart for pointing out the errors contained in the report and he believed that the chairman of the committee deplored the errors as much as anyone

After some further discussion the amendment was carried by a large majority

Dr W LLOYD ANDRIEZEN then delivered an address on the Stereoplasm of the Nerve Elements, a Study in Nerve Dynamics. The address was illustrated by lantern views.

Dr ERNEST W WHITE next read a paper entitled "Lunacy and Law the Care and Treatment of Persons of Unsound Mind in Private Houses and Nursing Homes," which was published in THE LANCET of Feb 14th, p 427

Dr OUTTERSON WOOD then read a paper on Lunacy and the Law which we hope to publish on a future occasion.

At the conclusion of the reading of the papers the PRESIDENT said that in the limited period at their disposal it would be impossible to have a discussion which would do justice to the subjects.

It was then moved by Dr OUTTERSON WOOD, seconded, and resolved that the discussion of the papers should be adjourned until the next meeting

In the evening the members dined together at the Midland Hotel at Derby The toast of "The Visitors" was replied to by Colonel GASCOIGNE, Dr C A GREAVES, and Dr E VAUDREY The health of the President was proposed by Dr YELLOWLEES

BRITISH ELECTRO-THERAPEUTIC SOCIETY —The annual meeting of this society was held on Jan 23rd, Dr W S Hedley, the President, being in the chair —Mr Edmund Owen was unanimously elected an honorary member —Dr Hedley then delivered his Presidential Address on Medical Electrology and Radiology in 1902 and also showed a double high frequency installation —The following members were duly elected officers for 1903 —President Dr H. Lewis Jones (London) Vice Presidents Mr W F Brook (Swansea) and Dr Donald Baynes (London) Council Mr W Armstrong (Buxton) Dr J Allan (Chislehurst) Dr David Arthur (London), Dr G B Batten (London), Dr James Barr (Liverpool), Dr J A. Codd (Wolverhampton), Dr S Sloan (Glasgow) Dr George Herschell (London) Mr C R C Lyster (London), Dr E. R. Morton (Taunton), Dr R. Milne Murray (Edinburgh), Dr S P Sunderland (London), Mr E W H Shenton (London) Dr E Solly (Harrogate), and Dr Hugh Walsham (London) Treasurer Dr H. W McClure (London) Honorary Secretaries Mr Chisholm Williams (London) and Mr. J F. Hall Edwards (Birmingham)

A number of important questions were raised at this meeting and many valuable facts were reported which ought to affect the attitude of the medical profession and of legislators alike towards this important matter

The question of the single care of persons of unsound mind is fraught with many difficulties. The forms of certification and the order for admission of a patient into the single charge of a responsible person are identical with those for admission of a private patient to an asylum or registered hospital with the exception that the medical attendant in the former case takes the place of the medical officer of the asylum The patient is visited at stated intervals and reports have to be made by the medical attendant to the Commissioners in Lunacy who periodically visit the patient. Thus abuses are guarded against and efficient official supervision is maintained There are undoubted advantages in the certified single care of private patients of unsound mind. First, there is the privacy which the rich as well as the poor desire alike, while facilities are given for the visits of friends. Secondly, there is the possibility of placing the patient in bright and home-like surroundings Thirdly, there is the avoidance of the "stigma" of treatment in a lunatic asylum. The defects and disadvantages of the treatment of lunatics as individual charges are few and remediable. The chief of these may be the absence of special medical treatment, since the medical attendant who visits the patient is, as a rule, a general practitioner or a physician with no particular experience in the treatment of mental diseases But the general health of the patient may gain by the attendance of a practitioner who is not a specialist. Unskilled nursing is another drawback, as the nurse (male or female) placed in charge of the solitary patient in the private house may be devoid of asylum training and experience The undue interference of friends or relatives is a source of trouble which is well known to retard recovery and which can hardly be avoided except in asylums But whatever may be the drawbacks met with in the system of certified single care they are remediable in many cases. This cannot be said of uncertified single care—the illicit and clandestine treatment of insane patients without certification. Being carried out secretly, without the cognisance and supervision of the Commissioners or Visitors in Lunacy, this system lends itself to abuses and dangers Dr WHITE and Dr OUTTERSON WOOD both cited in the papers read to the Medico-Psychological Association cases of abuse and even of barbarism in the treatment of patients under the system of uncertified single care. A joint committee of the Medico-Psychological Association and of the British Medical Association, which waited on the Lord Chancellor in 1899 gave information that numerous cases of insanity, including many so-called "borderland cases," were clandestinely treated in the country and in the Channel Isles to avoid certification, and showed that many cases of inhumane treatment had been found to exist owing to this, with the result that the chances of recovery for the patient were imperilled thereby As a consequence the Lord Chancellor introduced into the Lunacy Bill of 1900 a clause adapted from the existing Act in the Scottish lunacy law, of which the first section was as follows "If a medical practitioner certifies that a person is suffering from mental disease but that the disease is not confirmed, and that it is expedient with a view to his recovery that he be placed under the care of a person whose name and address are stated in the certificate, for a period therein stated not exceeding six months, then during that period the provisions of Section 315 of the principal Act shall not apply" The rest of the clause made provision for the notification of the fact to the Commissioners in Lunacy who could thus visit the patient, while on the other hand, the publicity of inquiry and the need of making a reception order by a magistrate were obviated. The patient had all the advantages of single care and incurred no "stigma" of publicity or of admission to an asylum. Incipient and unconfirmed cases of insanity could thus be placed and treated under conditions favourable to the patient, agreeable to the relatives, and consistent with the law of the land.

Similar advantages might be extended to patients suffering from insanity or mental unsoundness of a degree not demanding detention and treatment in an asylum or other institution Certain cases of acute and sub-acute alcoholic insanity, many types of borderland insanity, and those cases of insanity which depends upon definite and severe stress and which tends to pass away as the exciting cause disappears, constitute the class of cases suitable for care and treatment without certification and the publicity of a magistrate's order Notification to the Commissioners, as in the class of cases of incipient and unconfirmed insanity, would be sufficient to bring these cases under official cognisance and supervision and would thus prevent illegal and inhumane abuses, and a clause to this end could be introduced into the forthcoming Lunacy Bill The modification suggested by the Medico-Psychological Association in this matter is that in all cases of mental unsoundness in which certification and compulsory detention seem needless, and in borderland cases there should be a system of notification to the Commissioners in Lunacy to the effect that "A. B is a person of unsound mind and is *not* a proper person to be detained.' Such notification would be followed by a visit of a Commissioner in Lunacy or by someone deputed by the Commissioners. If a clause could be inserted into the forthcoming Lunacy Bill to give effect to this scheme another step would be taken in promoting rational and humane treatment and in diminishing the abuses of the law which are still prevalent in connexion with the clandestine treatment of the insane.

Annotations.

"Ne quid nimis."

THE ROYAL LONDON OPHTHALMIC HOSPITAL.

THE question of pulling down hospital buildings upon valuable sites that they may be rebuilt on other and less valuable sites has of late received a great deal of attention the attention not always being supported by accurate knowledge. Consequently when it was announced that the reasons which caused the committee of the Royal London Ophthalmic Hospital, known all over the world as the Moorfields Eye Hospital, to sell the site in the City and to rebuild elsewhere would be publicly discussed considerable had conferred on him the Honorary Fellowship of the College to which he was elected two years ago Lord ROBERTS, as will be seen by our report of his speech in another column, took the opportunity of bearing eloquent testimony to the work in South Africa of the Army Medical Service and its many and distinguished civilian coadjutors. We are grateful to the Commander in Chief for recalling that work to the public mind, and we would beg him to believe that in the Royal Army Medical Corps the country has a body of men who, if they receive fair and sensible treatment and proper opportunities for keeping abreast with scientific developments, can become some of the most valuable public servants possessed by the Empire. We are proud to welcome Lord ROBERTS as a titular member of our profession

◆

The Etiology of Cancer

IN THE LANCET of Dec 6th, 1902, p 1558, we published a leading article which drew attention to the arguments in favour of the contagiousness of cancer and pointed out the desirability of taking all possible precautions to prevent the spread of the disease. We have received a copy of a presidential address which Mr W GIFFORD NASH delivered at the annual meeting of the South Midland Branch of the British Medical Association in June of last year, in this address Mr NASH discussed the whole question of the causation of cancer Much of the evidence brought forward was quoted in the article to which we have referred, but there were several new facts of interest and importance. A striking case of auto infection which he observed is the following Mr NASH performed an abdominal hysterectomy for malignant disease of the uterus and at the time of the operation the vagina appeared to be healthy, but two months later numerous secondary nodules appeared in the mucous membrane where sutures had been inserted to close the upper opening of the vagina. He quotes some instructive observations of Dr BEHLA. The town of Luckau in Germany consists of a central portion with 3000 inhabitants, and eastern and western suburbs called Kalau and Sando, each of the suburbs having a population of 1000, thus making 5000 in all. From 1875 to 1898 no cases of cancer occurred in the western suburb, Sando, in the main portion of the town cases were not infrequent, while in the eastern suburb, Kalau, 73 deaths from cancer occurred out of a total of 663 deaths The soil of Kalau and of the main portion of the town was flat, low, and moist, that of Sando was elevated, sandy, and dry A stream or ditch encircled the main part of the town and the suburb Kalau, and it appeared that the cases of cancer followed the course of the ditch, and in Kalau, the suburb where cancer was very prevalent, all the gardens were watered from this ditch. The data are insufficient for the expression of any certain opinion, but there is great probability in the view that the semi stagnant stream was somehow causally connected with the great frequency of cancer in the suburb of Kalau The portion of Mr NASH'S address which was of special interest dealt with some investigations which he had made as to the distribution of cancer in Northern Bedfordshire. The total population of the district was a little over 100,000 and so afforded ample material for statistics of value. The period investigated comprised the ten years 1890 to 1899 With regard to the alleged increase in cancer in recent years Mr NASH thinks that the increase is apparent rather than real, and he bases this opinion on the fact that the earlier death certificates were frequently very inexact For instance, many deaths were attributed to "natural causes," "senile decay," and "consumption" Now it is not unreasonable to think that many of the cases of "consumption" in old people were cases of cancer Be this as it may, good cause is shown for thinking that some of the apparent increase in cancer is due to error Some very strong evidence in favour of the infectivity of cancer is supplied by facts collected by Mr NASH "Duplicate cases" are instances of cancer occurring in two or more patients in a house, or in near relatives who are in the habit of visiting one another, or in a person who has been nursing or waiting on a patient suffering from cancer 872 cases of death from cancer were investigated by Mr NASH and he found 30 houses in each of which two or more cases of cancer had occurred A good instance was seen in the village of Tingrith in the practice of Dr J WAUGH A man, T G, died from cancer of the lip in 1894 He was waited on by S D who died in 1897 from cancer of the ovaries. T G's wife died from cancer of the stomach in June, 1899 These were the only cases of cancer which occurred in that village during the ten years In another important series, W O, aged 71 years, died from cancer at Campton in 1876 His wife had cancer of the breast for eight or nine years and died in another house in 1886. M. S., aged 74 years, nursed Mrs. O and died in an adjacent house from cancer of the liver in 1893 Mrs. B, aged 73 years, occupied the same cottage as Mrs O after her death, and died from cancer of the umbilicus in 1892, and her daughter, aged 43 years, who slept in the same bed with her, died from cancer of the breast in 1896 From observations as to the altitude of the various villages in the district Mr NASH finds that there are more cases at heights above 300 feet than below 150 feet These results are important, as they do not accord with other observations He considers that the nature of the soil has very little influence on the occurrence of cancer but that the large number of instances where two or more cases occur in the same house or in persons intimately associated points to the disease being infectious. He urges that all the clothes and bedding used by a patient suffering from cancer should be destroyed and that care should be taken to disinfect thoroughly the room which the patient has inhabited

◆

Lunacy Law and Practice in Regard to Private Patients

THE address given at the meeting of the Medico-Psychological Association in November last by Sir WILLIAM GOWERS, upon Lunacy and the Law,[1] has served to bring out important papers presenting other points for consideration These papers were read at the last meeting of the Medico-Psychological Association of Great Britain and Ireland held at the County Asylum at Mickleover, near Derby, on Feb 12th, and one of them by Dr ERNEST W WHITE was published in THE LANCET of Feb 14th, p. 427

---

[1] THE LANCET, Nov 22nd, 1902 p 1369

about and spread disease," and he thought there should be power to enforce vaccination or revaccination among them unless they had a certificate of recent vaccination. If they would not submit they might be incarcerated until they had a proper mind on the subject Mr F Vacher, medical officer of health of the Cheshire County Council, thought that not only hawkers but all tramps should be licensed, an expedient somewhat difficult to carry out. Dr J B Wilkinson, medical officer of health of Oldham, illustrating the value of isolation, said that the stamping out of typhus fever would have been impossible if the cases had had to be treated in the slum dwellings where they most frequently occurred. In his opinion the majority of the 'return' cases of scarlet fever were due, not to premature discharge from hospital, 'but to the absence of proper precautions and thorough disinfection of all clothing at the patient's house" It is well to bear this in mind when considering the length of time that clothing is known to retain infection. Several lay members took part in the discussion. One gentleman thought that to make all tramps carry a licence would be considered too great an interference with the liberty of the subject and no doubt many may be found to hold that the subject ought to be allowed to be a nuisance and a danger to his fellow subjects. Alderman McDougall said that the tramp question caused great concern to members of sanitary authorities and he was glad to know it was engaging the attention of so many capable minds. Mr Wynter Blyth promised that Dr Young's suggestion that a sub-committee might draw up lines as to the investigation respecting scarlet fever would be considered by the institute.

THE FREEZING POINT OF MILK.

In a recent paper read before the Medical Society of Bologna and reported in *Il Policlinico* of Jan. 31st Dr Giuseppe Bellei discussed the application of cryoscopy in the analysis of milk. The freezing point of milk, he said, has been determined by many observers who have for the most part obtained concordant results, as it varied within very narrow limits there was an obvious interest in discovering how far it would be affected by ordinary and recognised modifications of the quality and the composition of milk. The thermometer used for this purpose is divided into hundredths of 1° C The apparatus has already been described and figured in THE LANCET by Dr Alexander Ogston [1] Dr Bellei examined 50 samples of milk obtained from different cowkeepers in the vicinity of Bologna, determining in each case the freezing point, the specific gravity the milk sugar, and the ash. He found that in the normal milk the freezing point varied from −0·53° C to −0·57°, the specific gravity varied from 1029 to 1033 without showing any relation to the freezing point, the milk sugar varied from 3·70 to 5·77 per cent., and the ash varied from 0·58 to 0·85 per cent. When the milk became sour the freezing point fell and continued to fall as the souring process progressed. Addition of water raised the freezing point, 10 per cent. of added water might raise it to −0·51° and could be determined with certainty by means of cryoscopy Simultaneous additions of water, starch, and dextrine produced no effect beyond that due to the admixture of water The freezing point of scalded milk was lower than that of normal milk, the addition of water in quantity sufficient to bring the specific gravity to 1030 or 1032 gave a freezing point of from −0·53° to −0·55°, so that it was not possible to distinguish scalded milk by cryoscopy The freezing point was not affected by the presence of small amounts of bicarbonate of sodium, salicylic acid, or boric acid, but it was lowered by the addition of two parts of formalin per 1000 of milk. Some further information relative to the behaviour of milk at temperatures near to its freezing point will be found in Mr. Henry Droop Richmond's "Dairy Chemistry"

THE DISTRIBUTION OF PLAGUE

DURING the week ending Feb 1st 4 cases of, and 2 deaths from plague occurred throughout all Egypt. Of the above cases 2 occurred at Barshoum el Koubra and 2 at Tant-el Ghezireh, Toukh district, Galoubieh Province. For the week ending Feb 8th 4 cases of plague occurred throughout all Egypt. Of these 3 cases occurred at Tant-El Ghezireh and 1 at Barshoum-el Koubra. As regards the Mauritius a telegram received at the Colonial Office on Feb. 13th states that for the week ending Feb 12th there were 4 cases of bubonic plague and 1 death from the disease. As regards the Cape Colony, the medical officer of health for the colony states that for the week ending Jan. 24th no case of plague in any human being has been discovered at any place in the colony At the end of the week one case of plague remained under treatment at the Plague Hospital, Port Elizabeth. Plague-infected rats have been found at Port Elizabeth during the week, the last being discovered on Jan. 18th.

THE ROYAL MEDICAL BENEVOLENT COLLEGE

THE council of the Royal Medical Benevolent College is about to make a determined effort to put the finances of the charitable side of the institution on a sound basis. For some years the absence of a small reserve of cash upon which to draw has been greatly felt, in consequence of which year after year money has had to be borrowed from the bankers at interest. At the end of the year 1900 £2500 were owing, at the end of 1901 £400 and at the end of last year £2900 In order to pay off a portion of this loan, and to meet current pressing liabilities, a part of the small amount of funded property of the institution was recently sold, and, unfortunately, since then expensive structural repairs have had to be undertaken at the College which will make the task of managing the finances still more difficult. The foundation stone of the institution was laid in July, 1853, and the scheme of the council is to raise a jubilee fund of £10 000 which would enable it to pay off the balance of the loan from the bankers, to meet all other liabilities, to re-purchase the stock which has recently been sold, and to put by a sum of money upon which to draw when, as will happen with all charitable institutions, a lean year occurs. The prospects of this jubilee special appeal are excellent, since H.R.H. the Prince of Wales has graciously consented, as has already been announced in these columns, to preside at the festival dinner on Wednesday, June 10th, in aid of the funds of the charity We are confident that nothing would please His Royal Highness more than to know that, as a result of his decision to select this dinner for his presidency the finances of the charity had been placed on a sound footing and that the system of practically living from hand to mouth had disappeared for many years to come Medical men, for whose benefit the institution exists, should, therefore, leave no stone unturned to make the dinner a financial success £10,000 is a large sum to collect, but considering that there are 37 000 members of the medical profession the work ought easily to be accomplished. Almost all should give something many ought to contribute liberally and a few could give largely Those who have wealthy patients might appropriately take this opportunity of enlisting their sympathy, since many persons realise that the payment of the medical attendant's bill rarely recompenses him for the anxiety and risk which he incurs. It behoves the profession to prove to His Royal Highness that his kindness in coming forward to help an important medical charity is fully appreciated. We are quite sure that whatever the treasurer, Dr interest was felt by the medical profession On Monday last, Feb 16th, the Lord Mayor opened 30 more beds at the new building of this institution in the City-road and occasion was taken to make a statement upon circumstances of very great medical and public concern. With regard to the general question of the removal of hospitals from old sites to new ones but little was said, which in itself showed that the speakers knew what they were talking about, for the wisdom or folly of removing hospitals must be judged on the individual merits of each case. There can be no general principle. With regard to the removal of the old Moorfields Hospital to its present site it can be pointed out against the policy which has been adopted that a big hospital unable to open its beds because of its heavy rates is, as far as the public is concerned, not so satisfactory an institution as a small but efficient hospital having all its beds occupied This is true, but in the case of Moorfields the hospital is said to have been quite unsuitable to the growing demands which were made upon it, and moreover it was intimated to the authorities by King Edward's (then the Prince of Wales's) Hospital Fund for London that a grant was given to the hospital only by reason of the fact that it was being removed to a new site. That the management of the hospital has been everything that could be desired is shown by the fact that the last annual grant of the Fund was £1100, with a special donation of £2500 towards the 30 beds which the Lord Mayor of London has now formally declared open In discussing the reasons which actuated the committee of management to remove to a new site the vice chairman of the committee, Mr H. Davison, admitted that the hospital had been removed from a site where they had lived almost rent free, and where they were subject to only a nominal amount for rates, to a new site where with a much larger building heavier expenses and rates were incurred. He pointed out, however, that though the committee was prepared for increased expenditure it did not expect that the rating authorities would treat the hospital on a different basis from that of similar institutions in the same district The rates paid by the Royal Ophthalmic Hospital were heavier than those paid by any hospital in London except St. Thomas's Hospital and Guy's Hospital. The old hospital was totally inadequate to deal with the increasing number of cases requiring relief, it was not in accordance with the requirements of modern surgery, and it was also insanitary Moreover, the old site did not cover a sufficient area for the erection of a new and adequate building Whatever might be said of its policy in removing, he claimed that no one could say that the committee had not acted in a businesslike way the last bill for the rebuilding had been paid and there was a credit balance of £600 The Lord Mayor, in reply to a vote of thanks, said with regard to the rating of hospitals that the time was coming, and coming very soon, when the question of some aid to the hospitals from the rates would have to be considered. If the authorities would not exempt hospitals from taxation but insisted upon exacting from them every farthing they possibly could the question would have to be considered whether the local authorities should not be made to contribute to these institutions. Our readers know that we are not in favour of rate-supported hospitals for several obvious reasons, the first and principal of which is that the rating authorities would not be able to obtain medical service comparable to that which is now given gratuitously to our noble medical charities But although we do not desire to see our hospitals supported out of the rates and therefore placed under the jurisdiction of the rating authorities we certainly consider that the debt of the community to the charities should be acknowledged by some remission of the rates upon hospitals and similar institutions. The question is a very large one and, as the Lord Mayor said, is one that calls for immediate consideration. We hope that he will assist to keep it before the public eye.

---

[1] THE LANCET Nov 9th, 1901, p. 1253.

SESSIONAL MEETING OF THE SANITARY INSTITUTE

IT was suggested at the congress of the Sanitary Institute in Manchester last September that occasional meetings should be held in large centres of population for the discussion of questions relating to sanitation. The first of these meetings was held in Manchester on Feb 7th at the Municipal School of Technology, under the presidency of Mr A. Wynter Blyth, chairman of the council of the institute. There was a good attendance Dr Meredith Young, medical officer of health of Stockport, opened a discussion on the Removal and Isolation of Infective Patients in Populous Districts With regard to such diseases as small pox and typhus fever there was no question as to the usefulness of segregation Scarlet fever was a disease requiring "peculiar delicacy and care in the matter of isolation." Referring to Dr O K. Millard's recent writings on the subject and to the untoward occurrence of "return" cases, he said that his indictment might now be looked upon as an attack, not so much upon hospital isolation *per se*, as upon isolation hospital administration, and he believed that when care was bestowed on the lines laid down by Dr J Niven and Dr W J R. Simpson the benefits ensuing on the isolation of other infectious diseases would manifest themselves in connexion with scarlet fever. He urged that all investigations as to hospital isolation and its effects on the occurrence of complications and on mortality should be carried out on similar lines, so that a greater accumulation of facts and figures might be available. He submitted, therefore, that lines of inquiry and suggestions as to the mode of investigations should be drawn up by a sub-committee of the Sanitary Institute, and sent out to all medical officers of health willing to carry out an investigation. He advocated a more extensive course of instruction for medical students in infectious diseases and asked if it were not almost a scandal that a training of only a few weeks' duration should be given in a branch of knowledge on the possession of which the safety of large populations frequently hung He spoke with no uncertain voice as to the measures for the repression of small pox. If asked "to choose one, and one only, he would unhesitatingly throw to the winds notification, isolation, disinfection, quarantine, 'Leicester' system, or any other system, and pin his faith wholly and solely to universal vaccination." In these days of vacillation and timidity as to vaccination, of yielding to the tyranny of the minority, to which we owe the present widespread epidemic of small pox, with its many deaths, the trouble and distress that accompany it, and the expenditure on account of it going on all over the country—which in the aggregate must be enormous—it is refreshing to have a definite statement from one whose position and experience lend weight to his opinion Mr T W H. Garstang, medical officer of health of Bucklow, said he was satisfied that in country districts hospital isolation reduced the prevalence of scarlet fever and that hospital nursing was infinitely preferable for any individual patient to the casual home treatment in the houses of the working classes Mr E. Sergeant, medical officer of health under the Lancashire County Council, agreed as to the advantages of isolation in scarlet fever and said that there should be the same medical supervision over the admissions as over the discharges, for he had known of cases admitted where the patients were not suffering from scarlet fever at all. He attributed the spread of small pox largely to the vagrants who went about the country 'These tramps, these parasites, who were a nuisance to society, were allowed to go that would come away easily was removed and during the dressing there was no bleeding but three-quarters of an hour later there was severe hæmorrhage. Gauze packing was performed and two and a half pints of saline solution were injected into a vein. Death occurred four hours later The necropsy showed a greatly dilated right ureter blocked at its vesical end by a calculus of about the size of a large bean. The kidney was converted into a sac containing purulent urine The bladder contained purulent urine and showed signs of inflammation There was an aneurysm of the abdominal aorta above the cœliac axis which had burst into the cellular tissue about the right kidney, forming a false sac, which was strengthened by a deposit of clot. The wound in the loin communicated with the sac, into which the gauze had been packed The vertebræ were eroded. The accident during the lumbar operation was different from that in which an aneurysm is opened by mistake for an abscess. Here a condition of the kidney requiring operation was known to exist and the correct route was adopted But on the way to the kidney was the false aneurysmal sac, the opening of which was unavoidable.

INTERNATIONAL CONGRESS OF THE MEDICAL PRESS

THE Second International Congress of the Medical Press will open at Madrid on Monday, April 20th under the personal presidency of the King of Spain. Dr Cornil, President of the International Association of the Medical Press, M. Cortezo, chairman of the organising committee, Dr Larra y Cerezo, secretary general of the congress, and the Spanish Minister of Instruction are expected to take part in the opening ceremony Among many interesting papers promised may be mentioned one on the Education of the Medical Journalist, by Dr Rodrigues Mendez, the Rector of the University of Barcelona, and a History of the Spanish Medical Press by Dr Larra y Cerezo Dr R. Blondel, secretary general of the International Association of the Medical Press, will make a communication upon the formation of an international bureau of scientific information and many important questions affecting the conduct and ethics of medical journalism are also set down for debate. Gentlemen desirous of attending the congress should communicate with Dr Larra y Cerezo 17, Léganitos, Madrid, concerning their subscription (25 pesetas, or 16*s* 8*d*) their lodging accommodation in Madrid, and reduced railway fares The same gentleman should also be informed immediately by anyone who desires to read a paper at the congress. All questions regarding the International Association of the Medical Press should be addressed to Dr R. Blondel, 8, Rue de Castellane Paris.

AN EPIDEMIC OF INFANTILE PARALYSIS

ONLY in recent years has the occurrence of infantile paralysis in epidemics been recognised In the *Boston Medical and Surgical Journal* of Dec. 11th, 1902, Dr Charles F Painter has described an epidemic which occurred in 1900 in Gloucester a seaport of Massachusetts with a population of 25,000 He gives notes of 31 cases which he examined in the months of June July and August, but some other cases also were observed by the local practitioners. Only one death occurred There was paralysis of the leg Three days later cerebral symptoms ensued and the child died in 36 hours from what seemed to be cerebro-spinal meningitis Unfortunately, a necropsy could not be obtained No definite cause for the epidemic could be traced but the majority of the cases occurred at, or more frequently from 24 to 36 hours after, periods of extreme heat. Sometimes the symptoms followed bathing in the sea. The following statistics of the epidemic are of interest. There were 23 males to nine females. The youngest patient was of the age of 13 months and the oldest of 10 years, 21 patients were of the age of three years or younger, eight were of the age of two years or younger, and seven were of the age of four years or older Dr. P Marie cites foreign epidemics of infantile paralysis as proof of the infectious nature of the disease. The following are the principal epidemics reported In the *American Journal of the Medical Sciences* in 1843 Colmer has described an "epidemic of teething paralysis From eight to 10 cases occurred within a radius of three miles in three months In 1881 Bergenholtz observed 13 cases in Umea, Sweden, in a period of six weeks Onhohm, in Mendal, Norway reported about the same time nine cases which occurred in six weeks in a small community In 1885 Cordier reported 13 cases near Lyons which occurred in June and July Calverly reported the greatest epidemic on record in the valley of the Otter river—126 cases with a mortality of 18. But some neurologists doubt the nature of the epidemic as the mortality was so high and there were symptoms suggestive of epidemic cerebro-spinal meningitis

NATIONAL HEALTH AND PHYSICAL EDUCATION

IN THE LANCET of Feb 14th, p 471, we published a letter under the above heading from Sir Lauder Brunton which commenced with a quotation from Burns. After we had gone to press we received another communication from Sir Lauder Brunton saying that he had doubts as to the accuracy of his quotation but that being away from his books he had no means of checking his reference. We have had neither the time nor the opportunity to collate all the editions of Burns but the passage is generally printed as follows —

> O wad *some* pow r the giftie gie us
> To see oursels as ithers see us.

Sir Lauder Brunton makes two additions to his letter which are as follows The first is with reference to the passage quoted near the end of his former letter, from Mr Francis Palmer's book, "Russian Life in Town and Country" and concerns the word 'artel." The meaning of this word is a small guild. Sir Lauder Brunton then goes on to say ' Since writing my former letter I have seen in the *Daily Telegraph* of Thursday, Feb 5th, p. 9, under the title 'Boy Smokers,' a still more staggering statement than Sir Frederick Maurice s At a meeting of the British Anti Tobacco and Anti Narcotic League on Tuesday, Feb 3rd, Dr T P Smith said that out of 11,000 young men who volunteered for active service during the late war less than 1500 passed the test of medical examination.

THE CURABILITY OF TABES DORSALIS AND OTHER PARA-SYPHILITIC AFFECTIONS BY THE INTENSIVE MERCURIAL TREATMENT

DR. LEREDDE of Paris, in a contribution to the *Philadelphia Medical Journal* of Jan 10th calls attention to this most important matter The "intensive ' mercurial treatment of tabes dorsalis and of general paralysis is one of the most recent developments in the treatment of cerebro-spinal diseases and an account has already been given in THE LANCET of some interesting results achieved in this respect by Dr Lemoine in the treatment of general paralysis[1] Dr Leredde declares that after having successfully treated a case of tabes dorsalis by this method and investigated thoroughly several cases of general paralysis which have recovered or improved markedly under treatment he is now convinced that these diseases may be regarded as essentially curable. The unsuccessful cases he points out, are due to incorrect treatment or to overlooking the presence of gross and irremediable organic lesions of the nervous

---

[1] THE LANCET Sept. 6th 1902, p 690

C Holman, and the officials can do to make this jubilee special appeal a success will be done, but their efforts will be of little avail if medical men fail to make a serious effort to help. A promised donation spread over a number of years will be almost as welcome as the money given down, and, needless to add, contributions of 5*s* and 10*s* will be gladly received. Most of our readers are doubtless aware of the work carried on by the institution. Pensions of £30 a year are given to 50 aged medical men or to the widows of those deceased and 50 foundation scholars, the sons of medical men in necessitous circumstances, receive free of charge an education of the highest class with board and clothing. To maintain the benevolent side of the institution a sum of over £6000 a year is required, the greater part of which is derived from voluntary contributions. To obtain this sum every effort of the treasurer and the officials has to be employed, so that we trust soon to be able to congratulate them upon the placing of their finances upon a sound basis, at any rate, for some time to come.

WHAT IS BAD AIR?

IT would seem to be a reproach to chemical science that at the present time we are not able to ascertain by its application the exact nature of the vitiating constituent of the human breath. Certain it is that the chief constituent added to the air by respiration—namely, carbonic acid gas—*per se* has little or no effect upon the health. Indeed, it has been stated that men can breathe for two or three hours without marked discomfort air which contains—with, of course, its full complement of oxygen—as much as 20 per cent. of carbonic acid and the presence of 1 per cent has not the slightest effect. But if the carbonic acid in the air be raised only to one-tenth per cent by human respiration the resulting air is most unwholesome and detrimental. There is no chemical difference, of course, between the carbonic acid gas of the human breath and the carbonic acid gas obtained from chalk or from the combustion of carbon or coal gas. The obvious deduction is that the carbonic acid gas of respiration has a poisonous companion and this companion has so far eluded all attempts at isolation and recognition. This poisonous constituent may occur as a constant quantity in relation to the carbonic acid gas, possibly it does not. We do not know, although it is very important that this point should be determined. We are content, however, to judge the impurity of air by measuring the amount of carbonic acid in it and to some extent this measure is a valuable guide. It is not satisfactory that the evidence of impurity is not obtained more directly than this. Everyone knows that air vitiated by human respiration is offensive and poisonous. In other words, bad ventilation—that is, a condition in which the products of human respiration are not removed—sooner or later produces toxic symptoms. There are usually loss of appetite discomfort, severe headache, and malaise which cannot be traced to infective organisms any more than the absence of such organisms can explain the curative effects of fresh air. Moreover, it is a common experience that a sojourn in a badly ventilated room occupied by a great number of people predisposes to disease. There seems little doubt that the impurity of the air has some connexion with the "catching of a cold." The presence of respiratory products is declared by an offensive smell and it seems odd that chemical analysis is not able to lay bare what actually the nose readily detects. The effect of bad air upon the health cannot simply be that of an offensive smell, though that undoubtedly plays a part. Quite recently chemical analysis and bacteriological analysis have at the instance of the London County Council been directed to the examination of the air of the tube railways. The results as might be expected, showed a considerable increase of carbonic acid gas in the air of the "tube" over that found in the air above ground, while micro-organisms appeared to be present in "tube" air in only a slightly greater proportion than in fresh air, and certainly the result was no worse than is shown by the examination of the air of an ordinary inhabited room. In other words, the carbonic acid of the air of the tube railways and the bacteriological flora found offer no satisfactory explanation of the admitted fact that that air is decidedly unwholesome and offensive. It not only is absolutely devoid of the vitalising effect of fresh air but it has also a most sickening smell and sooner or later gives rise to a sense of oppression. What is this poison? It seems to us that the whole question needs a much more extended inquiry than has been hitherto carried out, for surely chemistry and physiology hand in hand could eventually elucidate this matter. One point in regard to the smell of the air of the tube railways is, however, often forgotten—namely, that it is, in part at any rate, derived from the oil on the bearings of the engines and the machinery. We are certain that, however effectual the ventilation of the tube railways may ultimately become the air will never be free from the smell of machinery in motion.

CALCULUS IMPACTED IN THE LOWER END OF THE URETER WITH ANEURYSM OF THE ABDOMINAL AORTA RUPTURED INTO THE PERI-RENAL CELLULAR TISSUE

IN the *Intercolonial Journal of Australasia* for December Mr W Moore has recorded an extraordinary case in which two very rare conditions co-existed, rendering diagnosis impossible. A man, aged 44 years, was admitted to hospital on Oct. 20th complaining of pain in the abdomen and back which had confined him to bed for a week. Four days before admission he suffered much from vomiting. For three years he had suffered a good deal and for the last year had been almost continuously ill. Attacks of pain came on suddenly and generally were attended at the onset with vomiting. Sometimes he had a slight aching pain on micturition. He was wasted and sallow and his conjunctivæ were yellowish. The abdomen was full, especially above the umbilicus. The epigastric and right hypochondriac regions were slightly tender. With much misgiving Mr Moore performed exploratory laparotomy on Oct 27th, making an incision over the appendix which was found to be very long but not diseased and which was removed. This incision was closed and another one was made obliquely below the right ribs. The gall bladder and ducts were explored and were found to be normal. A large cyst in the region of the right kidney was tapped and fluid looking and smelling like urine was drawn off. The incision was closed, leaving a gauze drain. After the operation a small quantity of albumin was found in the urine. On Nov 3rd pus was found in the urine. On the 24th the right kidney was exposed by a lumbar incision. After dividing the aponeurosis and exposing the cellular tissue the finger was introduced and a sensation of something giving way was noticed. A little dark soft clot escaped and then there was such a gush of bright blood as to suggest that an aneurysm had been opened. The finger was kept in the opening and counter pressure was made on the abdomen, controlling the hæmorrhage. The wound was packed with iodoform gauze and sutured. When the wound was dressed on the next day the gauze plugs pulsated. There had been a little oozing of blood. On Nov 29th the patient could not pass urine which subsequently had to be drawn off. On Dec 3rd all the gauze addition to commencing the year with a deficit of £14 000 incurring, as they apparently intend to incur, an extra ordinary expenditure of over £30,000

THE PROFESSOR OF ANATOMY IN THE UNIVERSITY OF EDINBURGH

Professor D J Cunningham, F R.S. late Professor of Anatomy in Trinity College, Dublin, has been appointed Professor of Anatomy in the University of Edinburgh in the room of Sir William Turner, now Principal of the University Professor Cunningham's excellent practical and literary work are too well known to our readers to need any insistence upon from us, but it will be interesting to mention his obvious claims to his new post Professor Cunningham, the youngest son of the Principal of St. Mary's College, St. Andrews, was educated at the University of Edinburgh, where after taking his medical degree he became demonstrator of anatomy under Sir William Turner for six years, afterwards being elected Professor of Anatomy at Dublin, a post which he has now held for 20 years The Universities of Oxford, Cambridge, Edinburgh, and London, and the Victoria University, have all utilised his services as an examiner, while he has sat upon more than one Royal Commission. Professor Cunningham is one of those rare people, a thorough expert in his subject with wide knowledge outside it, and the loss to Trinity College, Dublin, is a heavy one

EXPENSES FOR MAINTENANCE OF PAUPER LUNATICS IN ASYLUMS

UNDER the provisions of the Lunacy Act, 1890, Poor law guardians are required to pay a certain sum per head per week for the maintenance of their insane poor in the county asylums. The amount of this weekly sum is fixed by the visiting committee of the asylum and it is subject to a revision every six months Changes are chiefly due to variations in the contract price of foods, clothing, and necessaries It is customary for the committee to supply the guardians with statements of the amounts to be charged during the following half year, but to the power of the committee there are limits They are indicated in the sub-clauses of section 283 of the Act above mentioned. To understand these limits it must be remembered that lunatics in an asylum may be grouped in two classes—those who have a "settlement in the county to which the asylum belongs and those who have settlements in other counties. For patients in the first named class the committee may fix the weekly cost per head at a sum not exceeding 14*s*, but sub-clause 2 gives power to the authority to whom the asylum belongs to increase the amount to any sum that 'seems necessary' provided that the order for such increase be published in a local newspaper For patients in the second class—namely, those who are in an asylum for a county in which they have not a settlement—the committee may fix under the terms of sub-clause 3, a sum not exceeding 14*s* It was to this second class that Eliza Whent belonged. She was a patient in the Essex county asylum, but she had a settlement in the Samford union, Suffolk. At the Brentwood county court an action was brought on Jan. 28th by the committee of the Essex county asylum against the guardians of the Samford union for recovery, for the maintenance of Eliza Whent, of a sum based on a weekly charge of £1 1*s*. The defendants declined to pay at a greater rate than that of 14*s*. per week, alleging that the committee could not legally charge, and that they, the defendants could not legally pay, any sum in excess of 14*s* for each week of maintenance. They contended that sub-clause 3 of section 283 of the Lunacy Act prevented the committee of the asylum from fixing a greater weekly sum than 14*s* His Honour (Judge Tindal Atkinson) gave judgment in favour of the defendants and he also gave leave to the committee to appeal. His Honour held that the resolution of the committee fixing the weekly cost of maintenance of each "out-county" patient at £1 1*s* was *ultra vires* We think that this decision is an important one. Unless it be reversed upon appeal or unless sub-clause 3 of section 283 be modified in the lunacy legislation expected in the near future a very anomalous state of matters will continue. We shall see authorities of county asylums charging guardians of their own county for their own county patients any weekly sum which 'seems necessary," while for patients who have settlements in other counties no greater charge than 14*s* per head per week can legally be made. From consideration of the above case we gather that to the list of faulty, contradictory, and indefinite clauses in the Lunacy Act of 1890 one more must be added.

WE understand that the report of the departmental committee on poisons has been issued, in which it is suggested that certain alterations relating to the regulation of the sale of arsenic tobacco extracts, and carbolic acid should be made. It is not surprising that a minority report is added, since the proposal to allow greater latitude in regard to the sale of poisons may be fraught with serious issues We hope to deal with this important report next week.

DR J S. Macdonald, professor of physiology at the University College, Sheffield, will lecture on "Nerve as a Concentration Cell" on Friday Feb 27th, at 5 P M, in the Physiological Laboratory of the University of London. Professor C S. Sherrington, Dr E. H Starling, Dr A. D Waller, and other physiologists are expected to join in the discussion of the subject.

THE annual meeting of the Coal Smoke Abatement Society will be held, by permission of the Duke of Westminster, at Grosvenor House, at 3 o'clock on Tuesday afternoon, Feb 24th. The Duke of Argyll, K.T, has consented to preside over the meeting and the speakers will include Lord Robert Cecil, K C, Sir James Crichton Browne, and Mr Shirley Murphy

THE next meeting of the Epidemiological Society will take place at 11, Chandos-street, Cavendish square London, W, on Wednesday, Feb 25th, at 8 30 P M. when a discussion will be opened by Dr Patrick Manson C M G, F R.S, on the Panama Canal and the Introduction of Yellow Fever into Asia.

A MEETING of the Neurological Society will be held on Thursday next, Feb 26th, at 8 P M., at 11, Chandos street, Cavendish square, London, W, and will be devoted to the exhibition and discussion of cases of Myopathic Muscular Atrophy

THE medical department of the Local Government Board has issued a report of an investigation which has been in progress for some years as to lead poisoning by means of water

WE regret to hear of the death of Mr W J C Miller, who was for over 20 years registrar of the General Medical Council.

CLIFTON DISPENSARY —The ninetieth annual meeting of the subscribers to this institution was held on Feb. 3rd under the presidency of the Rev Canon Wallace. The medical report stated that 3579 patients had been treated during 1902, including 73 midwifery cases, being an increase as compared with the preceding year The financial statement showed that the total income amounted to £755, and a small favourable balance remained.

system In the earlier stages of tabes dorsalis and of general paralysis when the symptoms are definite and the lesions have not involved actual destruction of nerve tissue—that is, when the morbid process consists mainly of vascular changes in the nervous system and of early nutritive degenerations of the nerve cells—the improvement obtained by cases under treatment which he cites has been so constant and enduring that he is confident in regarding them as cured. With Fournier of Paris Dr Leredde regards nine tenths of all cases of tabes dorsalis and of general paralysis as parasyphilitic affections and he cites the observations recently made by Professor Renaut on the morbid changes of the blood vessels in the early stages of syphilis which are curable under mercurial treatment. Similar changes mark the onset of tabes and of general paralysis and thus an anatomical basis, he considers, is found for the curability of these affections also

THE PREVALENCE OF SMALL-POX

THE following circular letters were recently issued by the Local Government Board for Scotland to the border counties and burghs , it may be of importance to other local authorities to be made aware of the present danger —

To the County Clerk.

SIR,—I am directed by the Board to request your serious attention to the rapid spread of small pox in the northern counties of England and to the probability of the introduction of infection to Scotland through the agency of vagrants.

It is a matter of observation by English local authorities at the present time that the disease is being conveyed from point to point by tramps. I am therefore to suggest for the consideration of the local authorities of your county the expediency of addressing a general warning to this effect to the inspectors of poor and parochial medical officers of the parishes adjacent to the border and also of communicating with chief constables with a view to securing the observation of such persons by the police I am, Sir, your obedient servant

(Signed) A. MURRAY,
for Secretary

To the Town Clerk.

SIR,—I am directed by the Board to request your serious attention to the rapid spread of small pox in the northern counties of England and to the probability of the introduction of infection to Scotland through the agency of vagrants

It is a matter of observation by English local authorities at the present time that the disease is being conveyed from point to point by tramps I am therefore to suggest for the consideration of your local authority the expediency of bringing this fact to the knowledge of your inspector of common lodging houses and of officials who have relations with the class in question including the police so that they may bear in mind the likelihood of encountering this disease

I am Sir your obedient servant,
(Signed) A. MURRAY,
for Secretary

A copy of the above circular letter was sent to the medical officer of health of each of the local authorities concerned.

THE EMBRYO-PATHOLOGY OF TUMOURS

A PAPER on the cause of cancer and other tumours, with suggestions as to the line of research to be taken up for the discovery of a cure for cancer, was read before the Royal Society of Edinburgh on Feb 16th by Dr John Beard, lecturer on embryology and vertebrate zoology in the University of Edinburgh. He showed that tumours are referable (1) to abnormal attempts at development on the part of one or more vagrant or aberrant germ cells, and (2) to the bizarre pathological manifestation by such of some greater or less portion of the life cycle of normal animal development. He is altogether opposed to the hypothesis of "rests" of embryonic organs, according to which many pathologists, following Cohnheim have attempted to explain the formation of tumours by a sudden awakening of such "rests" into activity He maintains that germ cells never arise at the first division of the fertilised egg and that there must always be a number of cleavage products not concerned in the formation either of an embryo or of germ cells These products give rise to an asexual foundation upon which the germ-cells, and with them an embryo, take their origin In human development this foundation, the chorion, is always present before any trace of an embryo appears. It is never the task of the fertilised egg to give rise directly to an embryo, but rather to a set of germ cells, each and every one of which may develop an embryo If in the human subject two such germ cells develop with abnormalities on the part of one there may result a more or less rudimentary embryo, or what has been called an embryoma by Professor Max Wilms—i.e., a tumour It apparently never happens that all of the primary germ cells find their way to the normal position for furnishing the foundation of the reproductive products A portion of them come to lie in one or other of very many abnormal positions, so that hardly a single organ of the body is free from the risk of possible "infection" by such vagrant germ-cells which are endowed with great potentialities for mischief Dr Beard has already explained his views in an article published in THE LANCET of June 21st, 1902, p 1758, and has there made the suggestion that if a vagrant germ cell skips the part of the cycle immediately before it its normal development may lead to the pathological formation of the representative of a chorion possessed of unlimited powers of growth, a cancer The continuation of his argument is somewhat as follows. In every normal development the chorion or syncytium commences to degenerate at a well-defined epoch, the so-called "critical period," and if it did not do so its further unrestricted growth would lead to a form of cancer—deciduoma malignum or chorion epithelioma. The degeneration of the chorion and with this the arrest of its growth are in all probability brought about by some substance either contained within the fœtal allantoic placenta or present in the blood of the fœtus, and just as the fœtal allantoic placenta or the fœtal blood can induce degeneration of the chorion, so it ought to be possible from allantoic placentæ or fœtal blood of animals such as the pig to prepare an extract or a serum with potent workings upon the cells of cancer

CHARING CROSS HOSPITAL

THE eighty second annual report of the council of Charing Cross Hospital lies before us and from it we learn that the nurses' new home is practically complete whilst the rest of the new buildings are making good progress. The two notable events of the past year were the laying of the foundation stone of the new buildings with full masonic ceremony by the Grand Master of England, H.R.H the Duke of Connaught, and the festival dinner at which the Duke of Fife presided. At this dinner the total sum collected was £5477 and we can cordially indorse the Duke of Fife's words in which he expressed the urgent need for new buildings and new arrangements for the hospital. Also it is certain that the hospital does admirable work and is obviously a boon to the neighbourhood in which it is situated. It has been said that the hospital should be moved. We do not think so, but the concluding sentences of the report of the council give cause for reflection The council says that it "cannot but view the present financial situation of the hospital with considerable anxiety The past year has been unfavourable for obtaining money The year 1903 begins with a deficit of £14,000 The amount required for the maintenance of the hospital and convalescent home is £17,000, of which £15,000 has to be raised from benevolent sources. In 1902 the extraordinary expenditure amounted to £33,000 It is not likely that a less sum will be required this year, making a total of £62,000" In the year 1900 we see by Burdett's 'Hospitals and Charities' that the extraordinary expenditure amounted to £3573, so we take it that the addition of some £29,000 to the extraordinary expenditure is due to charges for sites and for building We have no doubt that new accommodation and increased space are urgently required if the hospital is not to fall back in its good work, but we think that the authorities might well pause before, in people preferring margarine to butter or chicory to coffee gives no excuse to dealers to sell a mixture of the two as butter or coffee respectively We are inclined to favour the view that a thoroughly matured all malt spirit is, physiologically speaking, better than a grain spirit. Grain spirit can undergo but little change with age because there is nothing in it practically but alcohol, although, of course, there can be little doubt that when it is stored in sherry casks it may take up vinous principles and ethers may be gradually formed. One reason why the choice of a whisky may fall upon an all malt spirit is that when grain spirit is added to swell the volume of the blend there is no protection against the use of a very physiologically bad spirit for the purpose and there is no guarantee that the diluent employed is free from reproach. Indeed, we suspect strongly that bad whiskies owe their origin to this practice Bad whiskies are probably never all malt whiskies

What is the remedy? For one thing we should like to see it insisted that upon the label of the bottle of all spirits there shall be printed a clear statement of the nature of the contents whether the spirit be an all malt whisky or partly malt and partly grain spirit, or an all grape brandy or partly grape and partly grain spirit, and so forth. There can be no valid objection to the sale of mixtures so long as they are sold as such, but obviously it is fraudulent to sell a mixture when a pure unmixed spirit is expected or asked for Again, it seems to us that it would not be adding very much to the duties of the Excise authorities if they were to undertake the control of this labeling and accurate description of spirits, for the Inland Revenue Department must know exactly the pedigree and history of all the spirit produced in the United Kingdom We understand that certain distillers have approached the Inland Revenue Department upon this point, with the view of that department exercising a system of control by which the age and nature of spirits could be guaranteed to the public. In this connexion our attention has been drawn to a system of municipal control which has been adopted in Schiedam. In order to prevent the mixing of cheap spirit with "hollands" the municipality of Schiedam, in which town about 98 per cent. of the genuine hollands is made, has instituted special guarantee labels to be used on the bottles cases, and casks of the distiller who makes and sells nothing but the genuine article and places his distilleries under the control of the municipality The distiller who is desirous of enjoying the privilege of the system must allow the officials to inspect not only his different distilleries and refineries but also his Excise accounts as entered by the Government inspector concerning the spirit brought in or taken out of the premises He further must keep a register of the labels which he has received from the municipal authorities showing how they have been used and this must correspond with the Excise documents The effect of such a system, even although it has only been in operation for a short period, has been, it is stated very satisfactory in spite of the opposition of certain exporters who were naturally averse to the innovation, since it was calculated to deprive them of the great profits which they made by mixing the genuine article with a very large proportion of cheap spirit

All honest merchants and dealers in spirits in this country would, we are convinced welcome the introduction of a similar system of control. In the light of recent revelations some such step is urgently needed, it would harass the dealers in cheap spirit of course, but it would be of unquestionable benefit to the community to have the assurance that the label on the bottle describes correctly its contents. In such a case the truth about the public taste would soon become evident.

MEDICINE AND THE LAW

The Camberwell Murders.

EDGAR EDWARDS, or Edwin Owen as his name was stated to be by the one witness called on his behalf at his trial, was on Feb 13th sentenced to death by Mr Justice Wright at the Old Bailey He was convicted of murdering William John Darby, with his wife and child upon evidence that allowed no shadow of doubt as to his guilt, although, to use a term of which the late Sir James Fitzjames Stephen strongly disapproved, it was entirely circumstantial, for no one ever saw the murderer in the company of any of his victims or had ever heard him express ill will against them. The defence raised, so far as the thankless task of raising a defence was attempted by his counsel was that of insanity It was supported by no medical evidence, but a witness who said that he was the prisoner's uncle by marriage informed the court that the prisoner's mother's brother lived and died a lunatic, that the prisoner's maternal grandfather had a married sister who had been in a lunatic asylum, and that one of the witness's daughters—that is to say a first cousin of the prisoner—was now under control. He added that the prisoner's father died a confirmed dipsomaniac, having squandered in drink the fortunes of himself, his wife, and his two sisters. This is the kind of family history which, if it had been so given that its truth could have been tested and relied upon, might well have paved the way for medical evidence of insanity in the prisoner himself had the defence been able to call any It was, however, unsupported by any medical evidence and Dr James Scott, medical officer at Brixton Prison, who had kept the accused under close observation went into the witness box and said that he had seen nothing to indicate mental derangement. The prisoner's counsel dwelt upon the smallness of the motive that prompted the crime, but smallness of motive is no new thing in murder cases. The prisoner apparently tried to support the suggestion of insanity by a demeanour which no doubt seemed to him appropriate and by the exhibition of callous insolence even when sentence was being pronounced upon him. Probably the learned judge was right when he said that there might be some unsoundness of mind to account in a measure for his acts He is an able bodied and apparently not unintelligent man who might have earned an honest livelihood, but instead has lived a life of crime and spent nearly 15 years of his life in prison This fact was kept from the public until the trial was over Such a life and such an act as the murder of the Darby family are not characteristic of normal moral instincts and inclinations, there is nothing, however, in them to indicate that the convict who has now reached the end of his career did not do all that he did with full knowledge of its wickedness, deliberately accepting the possible consequences, while he took all the steps in his power to avoid them.

Physical Infirmity as an Incentive to Almsgiving

Beggars have probably made a living out of the exhibition of physical infirmities and deformities, real or simulated, ever since mendicancy has existed and others have increased their gains by taking with them children because those who give without thought or inquiry have a vague idea that to give to the ostensible parent benefits the unfortunate child It is to be hoped that some of these promiscuous almsgivers will have had brought to their notice the case of a man whom Mr Justice Grantham has sentenced to a richly deserved term of ten years penal servitude at Manchester Assizes A little girl, six years of age, living with her mother at Manchester, had had the misfortune to lose a leg which had been amputated, and this condition of the child appears to have excited the cupidity of the prisoner, himself a one-armed man and no doubt accustomed to excite commiseration on that account, for he made some sort of offer for the child to the mother which was naturally refused. Failing to secure his victim in this way he deliberately kidnapped the little girl who had been left outside a shop in a perambulator by her parent, and he also eluded the police, to whom complaint was forthwith made. For three months he dragged the child round with him, making her go on crutches so as to secure the full measure of compassion that he desired and sleeping with her at common lodging houses. His tour was presumably not unprofitable for having exploited Scotland as far as Edinburgh he seems to have crossed to Ireland and to have gone, at any rate to Dublin before returning to the North of England. At last, however he attracted the attention of an officer of the National Society for the Prevention of Cruelty to Children, or of someone who had the good sense and humanity to inform that organisation, with the result that he was arrested and sentenced to three months imprisonment for exposing the child to unnecessary suffering His offence would have been cruel enough if the matter could have been allowed to rest there. It was discovered however after he had been committed to gaol that he had added to his inhumanity by outraging his poor little victim and it was for this crowning iniquity that he was tried and sentenced at Manchester. Why he should have been allowed to be at large so long we

THE PRACTICE OF SUBSTITUTION IN THE SPIRIT TRADE

NOWADAYS the art of substitution would appear to permeate every trade, and it is usually justified on the apparently philanthropic ground that it is all for the public good, although any reference to the effect that the substitute is invariably a much cheaper article than the original product is seldom made For example, it is urged that jam can no longer be made with cane sugar because it crystallises and therefore a certain amount of glucose must be added in order to keep the preserve in a more or less fluid condition. Again, beer, we are told, can no longer be made from hops and all malt and so glucose must be introduced in order to prevent, it is asserted, a muddy product. Some, again, such is their taste, are said to prefer chicory to coffee, while others would have us believe that butter is inferior to margarine.

The latest controversy upon the subject of substitution has centred round whisky and a good deal has been said as to the merits and demerits of grain and malt whisky It is significant perhaps that this discussion should have arisen almost immediately after the results of THE LANCET Special Analytical Commission on Brandy were published, in the report of which the addition of grain spirit to whisky was incidentally referred to, and several communications upon the question from distillers in this and other countries have lately reached us. Doubtless to a great section of the public the recent discussion has appeared to them to be something of the nature of a revelation They will have realised that the trade done in so-called grain spirit is very considerable and that the destination of this spirit is largely whisky They must admit, also, in the light of our own inquiries, that a similar expedient is adopted with regard to brandy, and the conclusion is irresistible that a very demoralised state of things has overtaken a large section of the spirit trade. We are told that this practice of substitution is the outcome of a public demand but it is more probable that its adoption introduced a much wider margin of profit than was possible before Upon this point we may usefully quote the candid opinion expressed in an editorial article which appeared in connexion with this controversy in a leading journal of the spirit trade "The fact is that there has been—and the sooner it is confessed and amended the better —a great deal too much misdescription and mendacity even in the trade. Look at the labels which respectable houses put on their whiskies, particularly their cheap ones. Foaming cataracts tumbling through rocks and mountains and 'fine Highland' boldly put upon stuff that has not a 'fifth' of even 'malt' to bless itself with, let alone 'Highland' Then the plea that is put forward to palliate all this deception, 'The public prefer grain' Well, suppose they do, who taught them to prefer grain by giving them plenty of it? Let those who have been making such huge profits all these years answer the question It is the conveying of false impressions to the consumer at other people's expense to which we object. For all this masquerading of whisky in plaids and kilts and sporrans is done at the expense of the Highland distiller" Nothing could be more straightforward than the opinions thus expressed and it is to be hoped that they will appeal to the honest sense of the industry which this journal represents

The present position of the whisky business, according to this graphic description of its own representatives, is not without interest to our medical readers and it may be instructive to recapitulate the chief points of the controversy It is contended on the one hand that grain spirit is necessarily an impure spirit—that is to say, is unwholesome—and that, on the other, an all malt spirit duly matured is without prejudice to health. There can be no question that whisky originally was an all malt spirit grain spirit being a comparatively modern production Grain spirit in fact is the product of a patent still which effects a much more rapid separation of alcohol than does the old pot still, not only from the weak liquor in which it is generated, but also from the by products of fermentation Chemically speaking, therefore, grain spirit is a purer alcohol than all malt spirit because the latter contains volatile substances other than alcohol. It should be pointed out that the era of whisky began as soon as brandy fell into disrepute, which happened when the vineyards in the Charentes were ruined by disease in the late "seventies" Rightly or wrongly, the medical profession is generally credited with having brought whisky into favour by suggesting that well diluted, honest whisky was more to be trusted as a pure and wholesome form of stimulant than the wines and brandies at that time, which were undoubtedly the subject of considerable sophistication. But it is very important to bear in mind that in recommending the use of whisky for a specific purpose medical men could have had no other spirit in view but that made entirely from malt and matured by storage, for at that time the addition of grain spirit was not practised When whisky was ordered therefore an all malt whisky was prescribed.

"In cases of profound nervous and cardiac exhaustion one does not want merely an action upon the heart, but that stimulating influence upon the brain and vital centres which the volatile bye products seem to be alone capable of exerting Pot-still whisky, rum, and genuine brandy possess these bye products"[1] The substitution of grain spirit for an all malt spirit or the blending of malt with a large proportion of grain spirit thus raises a question of some medical importance, the physiological merits and demerits of grain spirit and all malt spirit respectively have, in short, to be considered. To begin with, the physiological effects of grain spirit must be referred practically to alcohol alone, since it contains little else. It is a pure spirit, without even *finesse*, it is flavourless or "silent," evidencing, that is to say, no clue to its origin. On the other hand, there is decided character in a malt spirit, it possesses a perfectly distinct flavour and a carefully conducted chemical analysis reveals certain products which are quite distinct from alcohol and to which its special characteristics as regards palatability, flavour, and bouquet may be ascribed. It is probable that these secondary or by products of fermentation and distillation modify in some peculiar way the physiological action of alcohol. They are even said to expedite the maturing process, or it may be that the secondary products of pot-still whisky yield more readily to oxidising influences than does "silent" whisky Certainly a young or raw malt whisky will create more physiological mischief than will raw grain spirit But a well matured all malt spirit is for some reason or other more wholesome and less harmful than either We are therefore led to suspect that there is a molecular rearrangement in the malt spirit containing secondary products by which the physiological action of the spirit is modified for good. In the same way young brandy is admittedly objectionable, while old brandy is acceptable, and yet the latter accumulates quite a high proportion of secondary products, such as aldehydes, ethers, and higher alcohols It is conceivable again that these secondary products may concentrate to such an extent as to render the spirit excessively potent though it may still be agreeable and mellow to the taste. Very old sherry or brandy, or even beer, are physiologically very powerful, while the taste is singularly mellow Again, what is described as "fat whisky" may have disagreeable effects in some individuals and on this account its dilution with a featureless spirit such as grain spirit is considered to be desirable in order to reduce the full bodied character of the all malt spirit. It does not follow, however; that an all malt spirit cannot be delicate in character or cannot possess *finesse* without recourse to attenuation with a foreign spirit Grain spirit, however, was introduced presumably to "break down" the "fulsomeness" of an all malt spirit, in reality it proved to be a cheap way of increasing the volume of a true whisky without diminishing its alcoholic strength, whilst preserving some of its malty flavour A similar practice prevails in regard to brandy, mixtures of a little genuine brandy with cheap grain spirit being very largely sold as the pure product.

Is the practice fraudulent? Is it likely to lead to injury to health? Of course, all alcohol from whatever source is, speaking generally more or less injurious to health but, at any rate, the consumer has a right to have some guarantee as to the nature or origin of the alcohol that is supplied to him. Otherwise he might as well buy common rectified spirit as spend a good deal more on an article with a fanciful or worse a misleading description. However opinions may differ as to the relative wholesomeness of all malt and grain spirit there can be no justification whatever for the substitution of the latter, or a mixture of the two, for the former The fact of some people preferring margarine to butter or chicory to coffee gives no excuse to dealers to sell a mixture of the two as butter or coffee respectively. We are inclined to favour the view that a thoroughly matured all-malt spirit is, physiologically speaking, better than a grain spirit. Grain spirit can undergo but little change with age because there is nothing in it practically but alcohol, although, of course, there can be little doubt that when it is stored in sherry casks it may take up vinous principles and ethers may be gradually formed. *One reason why the choice of a whisky* may fall upon an all malt spirit is that when grain spirit is added to swell the volume of the blend there is no protection against the use of a very physiologically bad spirit for the purpose and there is no guarantee that the diluent employed is free from reproach. Indeed, we suspect strongly that bad whiskies owe their origin to this practice. Bad whiskies are probably never all-malt whiskies.

---

[1] Foods and the Principles of Dietetics, by Robert Hutchison M D M R C P

What is the remedy? For one thing we should like to see it insisted that upon the label of the bottle of all spirits there shall be printed a clear statement of the nature of the contents whether the *spirit* be an all malt whisky or partly malt and partly grain spirit, or an all grape brandy or partly grape and partly grain spirit, and so forth. There can be no valid objection to the sale of mixtures so long as they are sold as such, but obviously it is fraudulent to sell a mixture when a pure unmixed spirit is expected or asked for. Again, it seems to us that it would not be adding very much to the duties of the Excise authorities if they were to undertake the control of this labeling and accurate description of spirits, *for* the Inland Revenue Department must know exactly the pedigree and history of all the spirit produced in the United Kingdom. We understand that certain distillers have approached the Inland Revenue Department upon this point, with the view of that department exercising a system of control by which the age and nature of spirits could be guaranteed to the public. In this connexion our attention has been drawn to a system of municipal control which has been adopted in Schiedam. In order to prevent the mixing of cheap spirit with "hollands" the municipality of Schiedam, in which town about 93 per cent. of the genuine hollands is made, has instituted special guarantee labels to be used on the bottles, cases, and casks of the distiller who makes and sells nothing but the genuine article and places his distilleries under the control of the municipality. The distiller who is desirous of enjoying the privilege of the system must allow the officials to inspect not only his different distilleries and refineries but also his Excise accounts as entered by the Government inspector concerning the spirit brought in or taken out of the premises. He further must keep a register of the labels which he has received from the municipal authorities showing how they have been used and this must correspond with the Excise documents. The effect of such a system, even although it has only been in operation for a short period, has been, it is stated, very satisfactory in spite of the opposition of certain exporters who were naturally averse to the innovation, since it was calculated to deprive them of the great profits which they made by mixing the genuine article with a very large proportion of cheap spirit.

All honest merchants and dealers in spirits in this country would, we are convinced, welcome the introduction of a similar system of control. In the light of recent revelations some such step is urgently needed; it would harass the dealers in cheap spirit of course, but it would be of unquestionable benefit to the community to have the assurance that the label on the bottle describes correctly its contents. In such a case the truth about the public taste would soon become evident.

MEDICINE AND THE LAW

The Camberwell Murders.

EDGAR EDWARDS, or Edwin Owen, as his name was stated to be by the one witness called on his behalf at his trial, was on Feb. 13th sentenced to death by Mr. Justice Wright at the Old Bailey. He was convicted of murdering William John Darby with his wife and child, upon evidence that allowed no shadow of doubt as to his guilt, although, to use a term of which the late Sir James Fitzjames Stephen strongly disapproved, it was entirely circumstantial, for no one ever saw the murderer in the company of any of his victims or had ever heard him express ill-will against them. The defence raised, so far as the thankless task of raising a defence was attempted by his counsel, was that of insanity. It was supported by no medical evidence, but a witness who said that he was the prisoner's uncle by marriage informed the court that the prisoner's mother's brother lived and died a lunatic, that the prisoner's maternal grandfather had a married sister who had been in a lunatic asylum, and that one of the witness's daughters—that is to say, a first cousin of the prisoner—was now under control. He added that the prisoner's father died a confirmed dipsomaniac, having squandered in drink the fortunes of himself, his wife, and his two sisters. This is the kind of family history which, if it had been so given that its truth could have been tested and relied upon, might well have paved the way for medical evidence of insanity in the prisoner himself had the defence been able to call any. It was, however, unsupported by any medical evidence and Dr. James Scott, medical officer at *Brixton Prison*, who had kept the accused under close observation, went into the witness-box and said that he had seen nothing to indicate mental derangement. The prisoner's counsel dwelt upon the smallness of the motive that prompted the crime, but smallness of motive is no new thing in murder cases. The prisoner apparently tried to support the suggestion of insanity by a demeanour which no doubt seemed to him appropriate and by the exhibition of callous insolence even when sentence was being pronounced upon him. *Probably* the learned judge was right when he said that there might be some unsoundness of mind to account in a measure for his acts. He is an able-bodied and apparently not unintelligent man who might have earned an honest livelihood, but instead has lived a life of crime and spent nearly 15 years of his life in prison. This fact was kept from the public until the trial was over. Such a life and such an act as the murder of the Darby family are not characteristic of normal moral instincts and inclinations, there is nothing, however, in them to indicate that the convict who has now reached the end *of his career* did not do all that he did with full knowledge of its wickedness, deliberately accepting the possible consequences, while he took all the steps in his power to avoid them.

Physical Infirmity as an Incentive to Almsgiving.

Beggars have probably made a living out of the exhibition of physical infirmities and deformities, real or simulated, ever since mendicancy has existed and others have increased their gains by taking with them children, because those who give without thought or inquiry have a vague idea that to give to the ostensible parent benefits the unfortunate child. It is to be hoped that some of these promiscuous almsgivers will have had brought to their notice the case of a man whom Mr. Justice Grantham has sentenced to a richly deserved term of ten years' penal servitude at Manchester Assizes. A little girl, six years of age, living with her mother at Manchester had had the misfortune to lose a leg which had been amputated, and this condition of the child appears to have excited the cupidity of the prisoner, himself a one-armed man and no doubt accustomed to excite commiseration on that account, for he made some sort of offer for the child to the mother which was naturally refused. Failing to secure his victim in this way he deliberately kidnapped the little girl who had been left outside a shop in a perambulator by her parent, and he also eluded the police, to whom complaint was forthwith made. For three months he dragged the child round with him, making her go on crutches so as to secure the full measure of compassion that he desired and sleeping with her at common lodging houses. His tour was presumably not unprofitable, for having exploited Scotland as far as Edinburgh he seems to have crossed to Ireland and to have gone, at any rate, to Dublin before returning to the North of England. At last, however, he attracted the attention of an officer of the National Society for the Prevention of Cruelty to Children, or of someone who had the good sense and humanity to inform that organisation, with the result that he was arrested and sentenced to three months' imprisonment for exposing the child to unnecessary suffering. His offence would have been cruel enough if the matter could have been allowed to rest there. It was discovered, however, after he had been committed to gaol that he had added to his inhumanity by outraging his poor little victim and it was for this crowning iniquity that he was tried and sentenced at Manchester. Why he should have been allowed to be at large so long we do not know, for procuring or causing a child of tender years to beg in the street is of itself an offence, but we have little doubt that the fact that the man had lost an arm and the little girl a leg induced many to regard them as afflicted persons whose only resource was mendicancy and that persons who might have rendered real assistance in the cause of charity at the expense of a little trouble and inquiry adopted the easier course of dispensing a few coins and passing on their way Medical men have some experience of beggars who trade upon their physical defects and are, as a rule, aware that among these are many as undeserving of charity as any not so afflicted With the general public the exhibition of a mutilated stump or the threat to exhibit it is a sure way to their pockets and of this the mendicant fraternity is well aware. To give alms without inquiry, as a rule, does no good , frequently it does harm and the motive for giving is usually a selfish one, the real object being to allay in the easiest manner possible a temporary pain or emotion aroused in the giver by an unpleasant sight or a tale of woe. In the case upon which we have commented those who gave helped an obviously professional beggar to prolong his brief career of crime and lust

THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS

LONDON OPEN AIR SANATORIUM, NEAR WOKINGHAM

A DEPUTATION of the National Friendly Society Conference has for some time been collecting information relative to sanatoriums for tuberculous patients and paying visits to various establishments of that description. In the autumn of 1902, soon after the holding of the first International Conference on Tuberculosis in Berlin,[1] the members of the deputation went to Germany to inspect the various sanatoriums and institutions provided by the State Sick Insurance Fund, and on Feb 7th they visited the London Open air Sanatorium near Wokingham which was inspected by the three winners of the King's prizes, and the plan of which closely resembles that laid down in Dr A. C Latham's essay The deputation was received in the absence of the chairman, Mr Rube, by Mr Malcolm A. Morris, the vice chairman, Dr A. P Hillier, one of the visiting physicians, and Dr C C Chidell, the medical superintendent. The sanatorium, which was built at a cost of £36,000, is mainly intended for tuberculous patients of the middle and poorer professional classes, who pay the low inclusive charge of three guineas a week The buildings are in the midst of 80 acres of pine woods and stand on sandy soil at an altitude of 220 feet. Each patient occupies a separate bedroom facing south and shelters, some of them lighted by electricity, are placed about the grounds. The visitors appeared to be very favourably impressed with the arrangements Two resident medical officers are in charge of the patients in the sanatorium. The secretary's office in London is at 20, Hanover square, W

HAILEY OPEN AIR SANATORIUM, IPSDEN, WALLINGFORD

In Germany there are hundreds of sanatoriums maintained by insurance societies which find it financially profitable to cure their subscribers rather than to pay the claims which the societies would have to meet were the disease allowed to run its course. In England there are a few municipal and gratuitous sanatoriums and a few others where the treatment is provided at a nominal fee Many patients, however, who return to their former unhealthy surroundings and dangerous occupations run great risks of relapse Sanatoriums may therefore be advantageously combined with working colonies where poor patients can be put in the way of fitting themselves for a useful out-door life after the cure has been effected An industrial sanatorium farm colony has just been opened at Ipsden, near Wallingford, by Dr C E. Reinhardt and Mr Frank Fowler, who conduct the Hailey Sanatorium, near Wallingford, and the Stourfield Park Sanatorium, Bournemouth, for wealthier patients At the Farm Colony Sanatorium patients are received at a small charge and are expected to work at such employment as the resident physician may find them physically and otherwise fit for , amongst other avocations they have the opportunity of learning pheasant-farming, poultry rearing, gardening, and various agricultural operations, in order to gain experience in such out-door occupations as may be useful to them after they leave the sanatorium.

DIDWORTHY SANATORIUM FOR CONSUMPTIVES.

On Jan. 23rd the Devon and Cornwall Sanatorium for Poor Consumptive Patients at Didworthy, Brent, was inspected by representatives of the urban and rural district councils of the two counties. At present it is intended to use the sanatorium for 14 patients—seven male and seven female—with a resident medical officer and nurses It is hoped that accommodation for 60 patients may be provided in course of time. The house and estate have been purchased by voluntary subscriptions for £4000 The additional cost of alterations, additions, laying out the grounds, and furnishing will be about £2500 Towards this sum there are £1000 in hand, leaving £1500 still to be raised, and the committee trusts that this sum will soon be forthcoming so as to enable it to open the institution in the spring free from debt.

WINSLEY SANATORIUM

A deputation from the Gloucestershire, Somerset, and Wilts Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis recently made an application to the Gloucester city council for a contribution towards the Winsley sanatorium scheme A sub committee of the council was appointed to consider the matter, when a motion was proposed to the effect that in view of the inadequacy of the Winsley scheme to meet the requirements of the city of Gloucester and the expenses connected therewith the council should take into consideration the question of using its power under the Public Health Act and of making its own provision for patients within the area of its control. Mr H. E. Waddy, surgeon to the Gloucester Infirmary, moved an amendment that the council should be recommended to accede to the application of the deputation to the extent of contributing £250 for the provision of one bed at the sanatorium and of paying £65 a year for maintaining it so long as the council may think fit to do so The amendment was lost and the original motion was carried. When the matter afterwards came before the city council for discussion Mr Waddy's amendment to give the contribution proposed was altered by the addition of the words "subject to a formal agreement being entered into containing terms satisfactory to this council," and in that form was adopted *nem. con*

RAILWAY COMPANIES AND SPITTING

The Great Eastern Railway Company has recently placarded Liverpool street station and other stations on their line with large posters printed in bold type, as follows —

> *Prevention of Consumption*
>
> To aid in the prevention of consumption and in their own interests, all persons are earnestly requested not to spit on the floor of any vehicle railway station or other public resort
>
> London December, 1902 J F S GOODAY General Manager

In the smoking carriages of the Central London Railway there are placards with the words "Please do not spit."

THE "STETHOSCOPE"

The first number of the *Stethoscope*, "a journal devoted to the cure or prevention of consumption," has just been published at 6, Duke-street, Adelphi, London, W C We wish our contemporary every success, but we nevertheless think that on ethical grounds there are some objections to articles headed "The Man of the Moment" as well as to the embellishment (!) of articles by likenesses of medical practitioners.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

MEETING OF THE COUNCIL.

AN ordinary meeting of the Council was held on Feb 12th, Sir HENRY G HOWSE, the President, being in the chair

It was resolved that diplomas of Membership should be issued to 96 candidates and that diplomas of Public Health should be issued jointly with the Royal College of Physicians of London to 18 candidates.

It was resolved that arrangements should be made for the delivery of six Hunterian lectures in November and that an advertisement should be issued inviting applications for election to the office of Hunterian Professor

---

[1] THE LANCET, Nov 1st (pp 1204, 1216) and Nov 8th 1902 (p 1276)

A report was received from the Committee of Management formulating a reply to the report of the visitor and the inspector of the General Medical Council upon the examinations in chemistry and biology of the Conjoint Board. The report was approved and adopted

The Council appointed Mr. Bernard Pitts a member of the Board of Examiners in Dental Surgery in the vacancy caused by the retirement of Sir William H. Bennett, K.C.V.O

The PRESIDENT reported that in pursuance of the provisions of the Bradshaw bequests he had chosen Mr Henry Morris as Bradshaw lecturer for the ensuing collegiate year

A report was read from Mr. REGINALD HARRISON upon the Cairo medical school and hospital. It was referred to the Committee of Management to consider in reference to the application by that school for recognition and a cordial vote of thanks was given to Mr. Harrison

A letter was read from the secretary of the Sanitary Institute reporting that the twenty first congress and exhibition of the institute would be held at Bradford from July 7th to 11th, 1903, and inviting the Council of the College to send delegates. It was resolved to leave it to the President to appoint delegates.

It was resolved to appoint a committee to consider and to report as to whether any and if so what, honorarium should be given to members of the Council called upon on behalf of the College to read essays submitted in competition for prizes

THE HUNTERIAN ORATION.

The biennial Hunterian Oration was delivered on Feb. 14th in the theatre of the College by Sir Henry Howse who in the later part of his address drew attention to Hunter's prevision of some of the results of modern geological inquiry The conditions under which fossil bones were preserved convinced him that animal life had existed on the earth for thousands of centuries, an opinion which was so much at variance with the accepted doctrines of the day that a geological friend advised him to alter the phraseology into "thousands of years." Rather than accept this compromise he withdrew the paper from being read before the Royal Society, as originally intended, and it was only published in 1859

THE BANQUET

The banquet in the evening was held in the library of the College. The President was in the chair and the company included Lord Roberts (the Commander in Chief of the Army) Lord Shand, Sir William Church, Sir Arthur Rücker, Sir Harry Johnston, Sir Thomas Smith, Sir Douglas Powell, Sir Henry Norbury Sir William Taylor, Professor James Dewar, Signor Marconi, and Professor Clifford Allbutt After the toast of 'The Memory of John Hunter" the PRESIDENT proposed the health of Lord Roberts whom he was about to admit to the Honorary Fellowship of the College. The Honorary Fellowship, he said, was not one of the old-established diplomas, in fact, it was only created by the Royal Charter which was granted on the occasion of the centenary of the College in 1900. Prior to the granting of this charter the College had not at its disposal any honorary title or mark of distinction which could be conferred on the foreign surgeons invited to attend the centenary celebrations. The list of foreign Honorary Fellows was augmented by the names of a few eminent personages in this country who were not surgeons. The present King, while still Prince of Wales, had been graciously pleased to accept a Fellowship and a similar distinction had also been conferred on two Prime Ministers. This Fellowship was honorary in the full meaning of the word, for the holders of it were not entitled either to practise surgery or to vote in the College. The Council had decided to offer it to Lord Roberts in view of the great services which he had rendered to his country as the general commanding in the South African war There were also special reasons for the medical profession feeling grateful to Lord Roberts, because it was doubtful if there had ever been a commander who had felt a greater interest in the medical organisation of the army or who had done more to help the military surgeons in meeting the unavoidable difficulties which they encountered. The President at the conclusion of his speech formally conferred the Honorary Fellowship on Lord Roberts.

Lord ROBERTS thereupon said that he had been for a long time looking forward with pleasurable expectation to this event and he now felt not only honoured by his new distinction but quite overcome by the cordiality of his reception. More than two years ago he had received a letter informing him that on the proposition of the late Sir William Mac Cormac the Council had agreed to offer him the Honorary Fellowship of the College, but as the war was still in progress he felt some reluctance to be the recipient of honours or rewards. Now that peace was secured he was delighted to be the guest of the College and the postponement of the ceremony had only served to add to the gratification which he experienced in being present. He was deeply sensible of the compliment which had been paid him and very proud to have inscribed his name on the rolls of the College. He accepted the honour not only for himself but for the navy, the army, and the auxiliary forces, to whom all the success that he was able to gain in South Africa was owing In speaking of the navy, the army, and the reserve forces it was not usual to particularise any section of them, but in the circumstances he could hardly avoid making special reference to the services of the Royal Army Medical Corps. Only those who took part in the war could thoroughly appreciate the devotion of the officers and men of that corps to their work, the arduous nature of the task which they had to undertake, and the admirable manner in which they fulfilled it. He was at Bloemfontein when enteric fever broke out there and for some time it seemed to him that it would hardly be possible to deal adequately with the enormous number of sick who had to be treated during the two months that the army was in that place. At Kroonstad, a few weeks later, the state of the case was perhaps worse, because the only available accommodation consisted of the church and one or two small hospitals and houses, but the way in which the medical officers coped with these emergencies excited his admiration. The Royal Army Medical Corps were greatly encouraged by the presence among them of the eminent civilian surgeons who came to South Africa, such as Sir William Mac Cormac, Sir William Stokes, Sir Frederick Treves, Mr. G L. Cheatle, Mr Watson Cheyne, Mr John Chiene, Mr. Clinton T Dent, Sir Thomas Fitzgerald, Mr. G H Makins, and many others. The skill and advice of these gentlemen were of very great service to the army in South Africa. In conclusion Lord Roberts said that he would always do his best to assist any scheme which might be for the benefit of the sick and wounded.

Mr JOHN TWEEDY proposed the health of "The Visitors," to which the Bishop of ROCHESTER and Sir HARRY JOHNSTON replied.

Sir A. RÜCKER proposed "The President and Orator" and the response by Sir HENRY HOWSE brought the proceedings to a close

Looking Back.

FROM

THE LANCET, *SATURDAY*, FEB 19, 1825

SIR ASTLEY COOPER AND THE BOROUGH PUPILS

SIR ASTLEY COOPER, after having been a Lecturer on Surgery at St. Thomas Hospital almost thirty years, has felt it necessary to resign the important duties connected with that office to others, who, being much younger in life, are more competent, physically to discharge those duties, and with whose scientific qualifications he is sufficiently satisfied to appoint them his successors.

It has been the practice, at the Borough School, to present each of the lecturers with a piece of plate on his resignation, and a meeting of the pupils was called to consider of the propriety of presenting Sir Astley with a similar proof of their respect. The meeting was held, and the proposition was negatived. The truth of the matter is this the pupils now attending the practice of the Borough Hospitals feel themselves aggrieved, because Sir Astley announced, by advertisement, his intention of continuing the anatomical lectures *jointly* with Mr Green. This has not been done, and we believe the indisposition of the worthy Baronet has been the principal cause of the non-performance of his pledge. Many of his pupils say 'we have not had the pleasure even of hearing Sir Astley once, and why should we become subscribers to a piece of plate?"

It is then, simply, because the students have not been made acquainted with the causes of the sudden resignation of Sir Astley as a lecturer, *in propria forma*, after his name had appeared in the advertisement, that they have to complain, and on this account only has any public opposition been manifested to the proposed measure.

We understand that, at a subsequent meeting, a paper was handed round for those gentlemen to subscribe who felt inclined, which was afterwards directed to be left at Mr Cox's library for signatures

According to a curious statement in the Philosophical Magazine, the extraordinary number of cases of cancer and schirrous complaints, in that part of Kent and Sussex bordering on Tunbridge Wells, has engaged the attention of several medical men in that district, who are endeavouring to ascertain its cause. A similar remark seems to apply to many other counties, where the poor feed much upon dried hogsflesh, and can get but little vegetable food.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8806 births and 4948 deaths were registered during the week ending Feb 14th. The annual rate of mortality in these towns, which had been 20 1, 18 1, and 17 9 per 1000 in the three preceding weeks, further declined last week to 17 1 per 1000 In London the death rate was 17 0 per 1000, while it averaged 17 2 per 1000 in the 75 other large towns. The lowest death rates in these towns were 5 7 in King's Norton, 8 0 in Barrow in Furness, 8 2 in Handsworth, 9 1 in Bournemouth, 9 2 in Derby, 9 3 in West Hartlepool, 9 4 in East Ham, and 10 0 in Coventry, the highest rates were 21 4 in Newcastle-on Tyne, 21 5 in Rochdale, 22 4 in Wallasey, 23 1 in Manchester, 23 2 in Bootle, 24 2 in Huddersfield, 26 4 in Hanley, and 28 8 in Tynemouth The 4948 deaths in these towns last week included 457 which were referred to the principal infectious diseases, against 540, 493, and 512 in the three preceding weeks, of these 457 deaths 131 resulted from whooping-cough, 91 from measles, 70 from diphtheria, 65 from diarrhœa, 59 from scarlet fever, 32 from "fever" (principally enteric), and 9 from small pox. No death from any of these diseases was registered last week in Bournemouth, Reading, Ipswich, Devonport, Burton on Trent, Wolverhampton, Handsworth, King s Norton, Bury, Stockton on Tees, or Swansea, while the highest death rates from the principal infectious diseases were recorded in Smethwick, Grimsby, Stockport, Wigan, Blackburn, Rotherham, Tynemouth and Merthyr Tydfil The greatest proportional mortality from measles occurred in Wigan and Manchester, from scarlet fever in Aston Manor and Stockport, from diphtheria in Northampton, Hanley, Blackburn, and Merthyr Tydfil, from whooping cough in Willesden, Great Yarmouth Smethwick, Grimsby, Stockport, and Rotherham, from "fever" in Walsall, and from diarrhœa in Middlesbrough Six fatal cases of small pox were registered last week in Liverpool and one each in London, Manchester, and Leeds, but not one in any other of the 76 large towns There were six small pox patients under treatment in the Metropolitan Asylums hospitals at the end of last week, against four, seven, and six at the end of the three preceding weeks, one new case was admitted during the week, against none, six, and four in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had declined from 2528 to 1941 on the seven preceding Saturdays, had further decreased to 1919 on Saturday, Feb 14th, 246 new cases were admitted during the week, against 227, 226, and 189 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 411, 355 and 315 in the three preceding weeks, further declined last week to 267 and were 179 below the corrected average number The deaths directly attributed to influenza in London last week numbered 24, having been 43 25, and 39 in the three preceding weeks The causes of 62, or 1 3 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in London, West Ham, Leicester, Nottingham, Salford, Bradford, Leeds, and in 38 other smaller towns, the largest proportions of uncertified deaths were registered in Hanley, Aston Manor, Coventry, St. Helens, Halifax, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 24 6, 21 3, and 21 7 per 1000 in the three preceding weeks, declined again to 18 1 per 1000 during the week ending Feb 14th, but was 1 0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10 8 in Perth and 14 9 in Edinburgh to 22 2 in Leith and 22 3 in Aberdeen The 594 deaths in these towns last week included 32 which were referred to whooping cough, 16 to diarrhœa, 15 to measles, 11 to "fever," eight to scarlet fever, and three to diphtheria, but not one to small pox. In all, 85 deaths resulted from these principal infectious diseases last week, against 102, 81, and 80 in the three preceding weeks. These 85 deaths were equal to an annual rate of 2 6 per 1000, which was 1 0 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 52, 32, and 28 in the three preceding weeks, rose again last week to 32, of which 22 occurred in Glasgow, three in Edinburgh, two in Dundee, and two in Leith The deaths from diarrhœa, which had been 13 and 19 in the two preceding weeks, declined again to 16 last week, and included eight in Glasgow, three in Dundee, and two in Greenock. The fatal cases of measles, which had been 20 and 16 in the two preceding weeks, further declined last week to 15, of which 11 were registered in Aberdeen, two in Glasgow, and two in Edinburgh. The deaths referred to different forms of "fever," which had been eight, five, and six in the three preceding weeks, further rose to 11 last week, and included 10 in Glasgow The fatal cases of scarlet fever, which had been five, four, and four in the three preceding weeks, increased last week to eight, of which four occurred in Glasgow and two in Paisley The deaths referred to diseases of the respiratory organs in these towns, which had been 183, 173, and 134 in the three preceding weeks, further declined last week to 112, and were 99 below the number in the corresponding period of last year The causes of 21, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 28 1, 24 8, and 26 4 per 1000 in the three preceding weeks, declined again to 25 0 per 1000 during the week ending Feb 14th During the past four weeks the death rate has averaged 26 1 per 1000, the rates during the same period being 18 3 in London and 18 1 in Edinburgh. The 182 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 10 from the number in the preceding week, and included 14 which were referred to the principal infectious diseases, against 10, 10, and nine in the three preceding weeks, of these, four resulted from diarrhœa, three from scarlet fever, three from whooping-cough, two from measles, one from diphtheria, and one from "fever," but not one from small pox. These 14 deaths were equal to an annual rate of 1 9 per 1000, the death rates last week from the same diseases being 1 8 in London and 1 3 in Edinburgh The fatal cases of diarrhœa, which had been six and one in the two preceding weeks, rose again last week to four The deaths from scarlet fever, which had been two, three, and two in the three preceding weeks, increased again to three last week. The three fatal cases of whooping cough corresponded with the number in the preceding week The 182 deaths in Dublin last week included 26 of children under one year of age and 46 of persons aged 60 years and upwards, the deaths both of infants and of elderly persons showed a considerable decline from the numbers recorded in the preceding week. Six inquest cases and three deaths from violence were registered, and 61, or one third, of the deaths occurred in public institutions The causes of 10, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1903.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1903

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1903	NOTIFIED CASES OF INFECTIOUS DISEASE. Small pox.	Scarlet fever	Diphtheria.*	Typhus fever	Enteric fever	Other continued fevers.	Puerperal fever	Erysipelas	Cholera.	Total.	Annual rate per 1000 persons living	DEATHS FROM PRINCIPAL INFECTIOUS DISEASES. Small pox.	Measles	Scarlet fever	Diphtheria.*	Whooping cough.	Typhus fever	Enteric fever	Other continued fevers.	Diarrhœa.	Total	Annual rate per 1000 persons living	Deaths from all causes.	Death-rate per 1000 living	Deaths of Infants under one year to 1000 births.

* Including membranous croup

With regard to the notified cases of infectious diseases it appears that the number of cases reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·5 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year In the three preceding months the rates had been 10·0, 9·1, and 7·4 per 1000 respectively The rates were considerably below the average in Paddington, Kensington, Hampstead, Stoke Newington, Lambeth, and Woolwich, while they showed the largest excess in Hammersmith, Southwark, Battersea, Wandsworth, Deptford, and Lewisham. The prevalence of small pox showed a slight increase over that recorded in the preceding month, of the 14 cases notified during January, three belonged to Fulham and two each to Islington, Stepney, and Poplar, while two others were notified by the Port sanitary authority The Metropolitan Asylums hospitals contained seven small pox patients at the end of last month, against 19, 17, and 14 at the end of the three preceding months, the weekly admissions averaged three, having been three in each of the three preceding months also The prevalence of scarlet fever, which had shown a considerable decline during the preceding month, further decreased last month, this disease showed the highest proportional prevalence in Hammersmith, the City of London, Southwark, Battersea, Wandsworth, Deptford, and Lewisham. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2820, 2705, and 2327 at the end of the three preceding months, had further declined to 1980 at the end of last month, the weekly admissions averaged 212, against 358, 301, and 236 in the three preceding months The prevalence of diphtheria showed a slight diminution from that recorded in the preceding month, among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Battersea, Wandsworth, Deptford, and Lewisham. There were 936 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of January, against 941, 1019, and 981 at the end of the three preceding months, the weekly admissions averaged 131 last month, against 149, 157, and 136 in the three preceding months. Enteric fever showed a considerable decrease last month as compared with the prevalence recorded in recent months, the greatest proportional prevalence of this disease occurred in Hammersmith, St. Marylebone, Hackney, Finsbury, Shoreditch, Bethnal Green, and Poplar The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 401, 339, and 210 at the end of the three preceding months, had further declined to 172 at the end of January, the weekly admissions averaged 24 last month, against 59 37 and 30 in the three preceding months. Erysipelas was proportionally most prevalent in Kensington, St. Marylebone, Shoreditch, Bethnal Green Stepney, Southwark, Bermondsey, and Camberwell The 19 cases of puerperal fever notified during the month included two each in Fulham, Islington, Hackney, Shoreditch, Southwark, and Lambeth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending Jan. 31st the deaths of 6455 persons belonging to London were registered, equal to an annual rate of 18·2 per 1000, against 16·0, 17·4, and 18·2 per 1000 in the three preceding months. The lowest death rates last month in the various metropolitan boroughs were 11·3 in Lewisham, 12·1 in Hampstead, 14·1 in Greenwich, 14·3 in Woolwich, 14·7 in Battersea, and 14·9 in Wandsworth, the highest rates were 21·7 in St. Marylebone and in Shoreditch 21·8 in the City of London, 22·1 in Southwark, 22·9 in Deptford, and 26·8 in Finsbury The 6455 deaths from all causes included 629 which were referred to the principal infectious diseases, of these, two resulted from small pox 156 from measles, 37 from scarlet fever, 63 from diphtheria, 272 from whooping cough, 31 from enteric fever, and 68 from diarrhœa, but not one either from typhus or from simple continued fever No death from any of these infectious diseases was recorded in Stoke Newington, among the other boroughs they caused the lowest death rates in the City of Westminster, Hampstead, Holborn, the City of London, and Woolwich, and the highest rates in St. Marylebone, Finsbury, Poplar, Bermondsey, Lambeth, and Deptford. The two fatal cases of small pox both belonged to Poplar The 156 deaths from measles showed a decline of 50 from the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Shoreditch, Bermondsey, Camberwell, Deptford, and Greenwich. The 37 fatal cases of scarlet fever were 20 below the average number in the corresponding periods of the ten preceding years, this disease showed the greatest proportional mortality in Hackney, Holborn, Southwark, Bermondsey, Deptford, and Greenwich. The 63 deaths from diphtheria were 114 less than the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Chelsea, Hackney, Poplar, Wandsworth, Deptford, and Greenwich, The 272 fatal cases of whooping cough were 91 in excess of the average number in the corresponding periods of the ten preceding years, among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Paddington, Kensington, St. Marylebone, Islington, and Finsbury The 31 deaths from enteric fever showed a decline of 21 from the corrected average number, the highest "fever" death rates last month were recorded in St Marylebone, Islington, Hackney, Shoreditch, Poplar, Wandsworth, and Camberwell. The 68 fatal cases of diarrhœa were slightly in excess of the average number in the corresponding periods of the ten preceding years, among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, the City of Westminster, Finsbury, Poplar Southwark, and Bermondsey In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 15 per cent. below the average.

Infant mortality in London during January, measured by the proportion of deaths among children under one year of age to registered births, was equal to 127 per 1000 The lowest rates of infant mortality were recorded in Holborn, the City of London, Shoreditch, Wandsworth Greenwich, Lewisham, and Woolwich, and the highest rates in Paddington, Hammersmith, Islington, Southwark, Bermondsey, and Deptford

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified —Fleet Surgeon J S Lambert to the *President*, for Survey of Stores at the Royal Victoria Victualling Yard, Deptford Staff Surgeons P B Handyside to the *Vengeance*, C S. Woodwright to the *President*, for three months' course of hospital study, and N L Richards to the *President* for Survey of Stores at the Royal Victoria Victualling Yard at Deptford. Surgeons H. E. Tomlinson to the *Egeria*, C A. G Phipps to Plymouth Marines (temporary), and H A. Julius to the *Pembroke*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J W Robinson assumes command of the Depôt and Training School at Aldershot, in succession to Colonel H. E R. James Lieutenant J A Black joins at Woolwich Captain F E Gunter is to be employed in China with the Legation Guard. Lieutenant-Colonel H R. Whitehead joins at Woolwich. Captain T J Crean, V C, joins at Aldershot and is posted to the 3rd Station Hospital for duty

ARMY MEDICAL RESERVE OF OFFICERS.

Captain William K Clayton, South Yorkshire Volunteer *Brigade Bearer Company*, to be Surgeon Captain. Dated Feb 14th, 1903.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) The Tynemouth Surgeon Captain H. R. Bramwell to be Surgeon Major Dated Feb 14th, 1903 *Rifle* 2nd Volunteer Battalion the Suffolk Regiment Surgeon Lieutenant-Colonel J S Holden resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. Dated Feb 14th, 1903 1st Volunteer Battalion the South Staffordshire Regiment Surgeon Lieutenant T Thompson to be Surgeon Captain Dated Feb 14th 1903. 21st Middlesex (the Finsbury) Surgeon Lieutenant Colonel J Adams to be Brigade-Surgeon Lieutenant-Colonel on appointment as Senior Medical Officer to the 5th London

Volunteer Infantry Brigade. Dated Feb 3rd, 1903. 4th (Donside Highland) Volunteer Battalion the Gordon Highlanders Brigade Surgeon-Lieutenant Colonel W Paterson resigns his commission with permission to retain his rank and to wear the uniform of the battalion on retirement, vacating at the same time the appointment of Senior Medical Officer of the Gordon Volunteer Infantry Brigade. Dated Feb 14th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

Glasgow Companies Lieutenant J Wright resigns his commission. Dated Feb 14th, 1903.

THE CLOTHING AND EQUIPMENT OF THE MODERN SOLDIER.

In a recently published pamphlet[1] Professor Krocker gives his views regarding the modern soldier's dress and equipment. The exigencies of military discipline impose on the soldier a form of dress which takes no regard of individual peculiarities and can only partially counteract atmospheric and climatic vicissitudes. The well being of the soldier's body under the greatly varying conditions induced while at work or reposing, in peace time or during war cannot be entirely safeguarded, and too often the requirements of hygiene have to give place to those of fashion. Formerly the protection of the wearer from the assaults of the enemy had to be taken into consideration by the uniform makers, but the soldier of the present day only wears armour by way of ornament. When he is ordered on active service cuirasses, epaulettes &c., are left behind. From the hygienic point of view two chief modifications should be aimed at by those responsible for the soldier's dress simplification and diminution of weight. For 40 years laudable efforts in this direction have been made throughout the military world, but it is in the German army especially that ornament has been sacrificed to utility In the brigade of occupation on duty in China the latest and most advanced ideas regarding hygienic clothing and equipment have been given effect to. It is manifestly impossible to devise a single suit of clothing which shall act as efficaciously in summer as in winter which shall maintain the temperature of the body within its physiological limits irrespectively of that of the air, while at the same time it protects the wearer from all atmospheric variations In a hot climate the clothing should absorb the least possible amount of solar caloric, but should not interfere with the free elimination of body heat, particularly in the form of sweat, whereas in a cold climate solar absorption should be encouraged and the heat of the body retained, but with the least possible impediment to both aeration and transpiration. Military clothing does not, as a rule, respond to these contradictory requirements. It is true that each man has a cloak and a segment of tent-cloth and also canvas trousers and jacket. He can likewise substitute a forage cap for his helmet and a pair of shoes for his boots, but hygienically speaking it would be well if he could be provided with two complete sets of clothes, inclusive of underclothing In the brigade of occupation already mentioned each soldier's kit was composed as follows three shirts and three pairs of drawers of light cotton, a pair of trousers and a blouse of khaki-coloured cotton three pairs of semi cotton hose, a cork helmet with neck protector and a khaki coloured cotton forage cap with peak. The above were for wear during the hot season For winter the following were provided two woollen shirts and two pairs of woollen drawers, trousers and coat of iron grey cloth lined with calico three pairs of woollen socks leathern helmet, and cloth forage cap. Extras one flannel vest and two flannel waist belts, two shawls and a pair of gloves. In addition fur pelisses and foot-warmers were served out to cavalry soldiers, the foot-warmers being attachable to the stirrups. Each soldier was also supplied with a hooded cloak, a canvas section, and a waterproof sheet. Professor Krocker's further remarks on the quality of military clothing and underclothing the influence of colour and cut foot gear, and equipment will repay perusal

THE ROYAL VISIT TO THE HERBERT HOSPITAL, WOOLWICH.

On Feb. 16th the King and Queen paid a visit to the Herbert Hospital, Woolwich and inspected the new nurses' quarters and the arrangements which have been made for the treatment of the patients. Their Majesties arrived at Well Hall Station at 3 20 P.M., where the King was presented with an address by the Mayor of Woolwich The Royal party then drove to the Herbert Hospital and on alighting at the entrance to the new nurses' quarters the King and Queen were received by the matron in-chief and members of the Advisory Board of Queen Alexandra's Imperial Military Nursing Service, Earl and Countess Roberts, General Sir T. Kelly-Kenny Surgeon General Sir William Taylor K C B, Director General A.M.S., Surgeon General A. H. Keogh, C B., Sir Frederick Treves, Bart., K.C V O, C.B, Major W G Macpherson, C.M.G, R.A.M.C, Lieutenant-Colonel H. R Whitehead, R A.M.C, in charge of the hospital, Lieutenant Colonel J J Lamprey, A.M.S (retired) Major M. O D Braddell, R.A.M C, registrar and secretary Major and Brevet Lieutenant-Colonel S. Hickson, R A.M.C Major Wilson, R.A.M.C, Major Cottel, R.A.M.C (retired), Captain K. M Cameron, R.A.M.C, and others After being shown through the re-constructed nurses' home Her Majesty expressed herself as being greatly pleased with all that she had seen and then examined the new uniforms of the nurses. The matrons, sisters, and nurses were afterwards presented with the badge of Queen Alexandra's Imperial Military Nursing Service by Her Majesty and the King and Queen then visited the surgical wards and conversed with the patients. In the operating theatre Sir Frederick Treves explained to His Majesty the use of some recent surgical appliances Before the Royal party left the building the King presented to members of the Royal Army Medical Corps the medal for South Africa.

DEATHS IN THE SERVICES.

Surgeon General Edward Baily Tuson, A.M.D (retired) at Chelston Manor, Torquay, on Feb 4th. He entered the army as assistant surgeon in 1844 became surgeon in 1854, surgeon major in 1864 deputy surgeon general in 1872, and retired with the honorary rank of surgeon general in March 1879 He served with the 12th Lancers in the Crimea in 1855 (medal with clasp and Turkish medal)

Surgeon Major William Venour, A.M.D (retired), on Feb 4th, at Netherwood, Saundersfoot, in his sixty ninth year He entered the army as assistant surgeon in 1858, became surgeon in 1873 and attained the rank of surgeon-major in 1875 He served in the Ashanti campaign in 1873 and was attached to the 15th Hussars during the Afghan war of 1878–80 and took part in the advance to Khelat-i-Ghilzie He was present at the affair at Takht-i Pul, in medical charge of a squadron of the 15th Hussars and a half battery of Royal Horse Artillery (medal). In the Soudan expedition of 1884 he was in charge of a hospital at the base, and in the Burmese expedition of 1886–87 he was in medical charge of a field hospital (mentioned in despatches for services in the Soudan and Burma)

NEW REGULATIONS FOR PROBATIONERS OF THE INDIAN MEDICAL SERVICE.

According to an order which has just been issued probationers of the Indian Medical Service will be placed on the same footing as those of the Royal Army Medical Corps. We hope to find room for these regulations in an early issue.

Correspondence.

"Audi alteram partem."

THE RISE OF BLOOD PRESSURE IN LATER LIFE

To the Editors of THE LANCET

SIRS,—Like Sir Douglas Powell, who has written in your issue of Jan 24th p 265 I much regret that I was unable to be present on the occasion of the reading of Professor T Clifford Allbutt's paper before the Royal Medical and Chirurgical Society on Jan. 13th. It affords me much consolation, however that I have been able to read not only the paper of Professor Allbutt but the comments thereon of Sir William H Broadbent, Dr Alexander Haig, Dr Newton Pitt, Dr H D Rolleston, Sir R Douglas Powell, and Dr William Russell and himself. I join in the chorus of thanks to Professor Allbutt who has conveyed to us lessons of scientific truth (*truth as I so interpret it*) in striking phrases and has given me (at any rate) much opportunity for thought in the future

It seems to be generally acknowledged that there is a condition of increase above the normal mean of intra arterial pressure in later life, but the causes of this increase are interpreted in a different manner by different observers The author of the paper, Professor Allbutt, considers that the chief factor is viscosity of the blood—I presume a condition brought about by a perverted metabolism which renders it difficult to circulate through the arterioles, capillaries, and venules. Sir William Broadbent and Sir Douglas Powell, however, consider that the chief cause of the obstruction which leads up to the increased intra arterial pressure is in the arterioles or the capillary network. It is all very well for Professor Allbutt to contend that vaso constriction cannot be a chief cause because it has been proved to be transitory[1] This would, no doubt, be valid if it were contended that it was the primary and only cause, but what if it is a partial cause coöperating with the blood change which he calls viscosity? Sir Douglas Powell says, as, I think, very pertinently, "Arterial contraction has also a more common cause, probably in the central nervous system." It is partly because I believe this doctrine to be true and partly because I desire to retain my inquiring mind that I venture to address you on this occasion For in the first place, though the arteriole contraction may be, according to the evidence of rigid scientific investigation, in the normal organism fitful and transitory it may be quite otherwise when perverted metabolism inducing a morbid blood change is in existence as a concurring or reinforcing cause. In this communication it is my earnest desire to be *practical* I know that for this sentence I deserve to be castigated by all those who have taken part in the discussion, from Professor Allbutt through the whole list As if they also were not practical! By practical this time I mean brief and perhaps unsatisfactory because not developing sufficiently the arguments in proof of the views I hold Let this therefore, be a mere statement, not an apology, nevertheless, I will, if cross examined, give reasons for the faith that is in me

---

[1] Jena: G Fischer 1902.

First of all I inquire of myself whether diseases, especially abnormalities of blood pressure and anomalies of circulation, have not in my own experience considerably changed within the last 12 years? My answer is Yes, they have. Is there a notable cause for this if true? I think so It is the presence or the frequent manifestation of a disease which we know as influenza What is the nature of the disease? It is infectious and due to a special microbe—the minute bacillus of Pfeiffer Has it, or have its toxins, any special manifestations which may go to elucidate the problem before us? In my opinion, emphatically yes. Its special manifestations are upon the nervous mechanism, on the peripheral nerves inducing neuritis varying and variable, on the spinal cord as I have myself traced,[2] and on the central nervous system as shown by the records of a host of observers The evolution of the disease process in influenza is extremely slow The degree of the initial symptoms bears no relation to the gravity of the symptoms of disease of the nervous mechanism which follow in its wake. In this regard we see, as was pointed out by the late Dr Althaus "an analogy with syphilis where the primary symptoms may be so slight that they attract very little attention and yet are followed by severe secondary and tertiary manifestations" Moreover, it is a matter of common experience that one individual may be infected many times. Immunity seems to be obtained with difficulty if at all, and furthermore the microbes and toxins of influenza appear to reinforce and to aggravate the effects of other microbic diseases and not in any sense to antagonise them. The bearing of these observations on the question at issue is that conditions of heightened arterial pressure have been greatly increased according to the observations of some men of experience in these later days in which influenza has been rife and in many of them the causal relation can be traced, as some of us believe, to the vaso motor mechanism

The question whether there has been, or may have been, any disturbance from this cause inducing a perversion of metabolism, wherefrom an increased viscosity of the blood may be at first sight more obscure I myself think, from clinical observation that there has been such a cause of perversion. It seems to me that in many persons of a later period of life in whom vices of metabolism might be looked for infection by influenza has come as a determining or aggravating cause. Of course this may be considered as a *petitio principii*, or a pious opinion mainly But in my mind the conclusion is forced on by a formidable series of clinical experiences. The sum of the whole matter, then, in my opinion, *quantum valeat*, is that Professor Allbutt is right in his conclusion that intra arterial pressure is raised in later life—a comforting conclusion in that it makes recovery from the earlier conditions hopeful and does not postulate an inevitable future arterio-sclerosis and that the causes of such condition of heightened arterial pressure are probably two-fold—a contraction of arterioles due to some morbid condition of the vaso-motor mechanism and a blood-change which may be termed "viscosity" The principles of treatment of the condition have been so ably though sententiously laid down by Professor Allbutt that I can serve no good purpose by attempting to add to them.

I am, Sirs, yours faithfully,

Harley-street W, Feb 11th, 1903 A. E Sansom.

To the Editors of The Lancet

Sirs,—I am gratified by the interesting and instructive letters which my comments upon Professor Clifford Allbutt's paper have brought forth and I would not have intruded further in the correspondence, for I agree with Professor Allbutt that the main points raised require further work for their elucidation, only I desire to explain what appears to have been an obscure sentence in my letter My argument was that inelasticity of degenerated vessels wasted the cardiac force and so tended to lower blood pressure. In order therefore to maintain the circulation at due pressure increased cardiac action was necessary and hypertrophy of the heart ensued. I think Dr Harry Campbell and I are at one in regard to arteriole contraction being the important cause of increased blood pressure, I used the more comprehensive, if less exact, term arterial contraction because it is very certain that arteries of medium calibre partake in the contraction and furnish the clinical index of it, although the resistance to circulation would chiefly exist in the smaller arterioles I have never been able to understand the mechanism of increased capillary resistance from altered conditions of blood which I remember was much insisted upon by the late Sir W Savory

In my poor attempt to interpret Professor Allbutt's term "increased viscosity" I implied that the altered blood so described brought about arterial contraction through excitation of the vaso motor nerves producing the hypertonus of vessels referred to by Dr Campbell, and I agree with his argument on this head, tonus and hypertonus being merely a matter of degree, indeed, in my Lumleian Lectures I spoke figuratively of the blood as being held in the grasp of the vessels to be tightened or relaxed at the behest of the nervous system. In bringing about this tonus and hypertonus, maintaining and regulating the blood pressure in varying and sometimes in morbid degrees, the suprarenal bodies would seem on clinical evidence to have an important function, witness the remarkable fall of blood pressure in Addison's disease and the toxic effects of adrenalin upon the vessels.

I am, Sirs, yours faithfully

Wimpole-street, W Feb 16th 1903. R. Douglas Powell.

To the Editors of The Lancet

Sirs,—Medical and scientific discussion ought to have two objects first, an attempt to see eye to eye, and, second, the clear and unambiguous defining of the points on which there is diversity of opinion For some time I have been contemplating a second paper on "hypertonus" and I thought that I could glean support from Professor T Clifford Allbutt's Lane lectures I wish to thank him fo making it quite clear that he and I do not look at th vascular phenomena under consideration from the sam standpoint. He looks from the physical standpoint, look from the vital, he is attracted by the behaviou of fluid in tubes, I am by the response of the *livin* tubes to their contained fluid I think it no mea gain to have positions so clearly determined. One furth word I should like to add, and that is to assure Profess Allbutt that in my choice of a word to express my apprec tion of his high literary faculty and attainments I regret have taken a word to which he attaches an unsavoury mea ing With reference to Dr Harry Campbell's valuab letter, while I agree with much of it I think that he pays t little regard to the action of the capillaries. He makes perfectly clear that he holds by the arterioles exclusively also note that he recognises hypertonus without rais pressure only "when the heart has come to the very end of its tether", in my experience it is much more common. These points can, however, be reserved for further discussion.

WILLIAM RUSSELL.
Edinburgh Feb 14th 1903

THE ABUSE OF MEDICAL CHARITY

To the Editors of THE LANCET

SIRS,—The defence of the administration of the Bradford Children's Hospital, published by the honorary secretary, Mr H J Jeffery, in THE LANCET of Feb 7th, p 398, to the charges made by the chairman of the Bradford board of guardians, calls for notice. It is not a little remarkable that Mr Jeffery does not make the slightest reference to your leading article on the abuses at that hospital, but only refers to the charges of the chairman of the guardians. The same policy of silence was pursued in 1898 when your Special Commissioner made a report on the hospital abuse in Bradford, the Children's Hospital being very severely criticised Then, as now, the board of that hospital took no notice whatever of your criticism and the abuses have continued unabated Such tactics may to some extent prevent that attention being drawn to the flagrant abuse of the charity which would be caused by an attempted defence of the hospital management against your criticism. But it cannot fail to suggest the idea of inability to make a successful defence, and it certainly produces a very unfavourable opinion of the board when one sees that it is content to lie under the serious charge of mismanagement of trust funds without one word of protest. There may be times when "silence is golden" but to preserve the attitude of deaf mutism when one is publicly charged with allowing charitable funds to be recklessly squandered is not usually regarded as dignified or proper Such an attitude is indeed startling

It is rather clever of Mr Jeffery not to mention in his letter to you the charges brought against his board. This careful suppression tends to obliterate them from memory, and on reading his defence cursorily one might imagine that an injured innocent had been accused of—nothing in particular But on contrasting his defence with the accusations it will be seen how inadequate it is. Indeed, Mr Jeffery virtually admits the truth of all Mr F H Bentham's charges. What Mr Bentham is reported to have said about the Children's Hospital, in his general condemnation of the management of all our hospitals, is as follows "The Children's Hospital has no recommendations Children were taken into the institution without inquiry into the circumstances of the parents, though they were required afterwards, if able, to contribute. He was told that in every case the parents word was taken, and he was not aware that any inquiries had been made through the C O S [Charity Organisation Society]. The committee received £104 from that source in 1901 for 213 children with an average attendance of 37 2 days In the out-patient department 2308 cases were dealt with. No inquiries were made into the circumstances and all comers were dealt with indiscriminately"

As Mr Jeffery does not make any reference in his defence to any of these various points except that as to 'inquiry into the circumstances of applicants for medical charity it may be assumed he admits they are all correctly stated—viz, (1) that the paltry sum of £104 was collected from parents of children who spent 7781 sick days in hospital, (2) that there were 2308 out-patients and that no inquiry is made about them unless deemed necessary by the board, (3) that the board does not avail itself of the assistance of the Charity Organisation Society, (4) that all comers are indiscriminately treated, and (5) the parents' word is accepted in practically all cases. It requires some attention to see that in Mr Jeffery's letter he is throughout only dealing with the 213 in patients, except where he once refers to 'all' patients

Now, what is Mr Jeffery's defence? 1. He says '*Very many* of the cases treated at the hospital [i e., in patients T W H.] are received on the recommendation of medical gentlemen in the town who naturally satisfy themselves that the position of the families is such as to justify an appeal to the charity In other words the board makes no inquiry as to "very many of the cases' The assumption that the medical men who send these cases act as inquiry officers could be no justification for the board's neglect. The assumption is further no doubt quite unwarranted. Medical men do not act as inquiry agents as to their own patients and certainly will not do it to relieve the board of its duty What "very many" cases means is uncertain. I would ask Mr Jeffery if it means as much as 1 in 100, until I have his assurance I must doubt if it means so many 2. "The bulk of the in patients," he says "are drafted into the hospital by the honorary medical staff from the out-patients' department, after careful examination and inquiry as to the circumstances of each family", in other words, he says, the honorary staff are the inquiry officers of the hospital, their inquiries are made while prescribing for the applicants, and their investigations are thorough and satisfactory How completely is the nature of a proper inquiry understood by Mr Jeffery and his board if he thinks such an inquiry sufficient! How utterly has the medical staff sunk from the dignity of their profession, if as Mr Jeffery alleges, while actually prescribing for the sick and suffering they engage in a minute inquisition of the means of the sufferers. I can say of one member of the staff that he indignantly repudiates having ever acted such an odious part as that of combined medical officer and charity organisation officer Supposing the medical officers did stoop to this meanness, which I will not readily believe, they must accept the statements of the parents alone, as Mr Bentham said.

It is obvious that the board does not take proper steps to safeguard the charitable funds intrusted to it. No doubt the staff will take occasion to repudiate the statement that they act as inquiry officers. I believe Mr Jeffery is misinformed as to the facts. No reference was made by Mr Bentham to the great abuse arising from the enormous number of quite trivial cases treated at this hospital (and at all the Bradford hospitals) or of the unnatural rate of increase of the number of patients, which has been out of all proportion to the increase of the population and the wealth of the city

I am, Sirs, yours faithfully,
Bradford Feb 10th, 1903 THOS. WHITESIDE HIME.

THE ANATOMY OF GLÉNARD'S DISEASE

To the Editors of THE LANCET

SIRS,—Dr John Knott has been good enough to criticise in your pages[1] and at considerable length a recent effort of mine to explain the manner in which the abdominal viscera become displaced. The explanation which I offered has proved entirely unsatisfactory to Dr Knott, especially in so far as it has upset certain preconceptions of his regarding the nature and action of the diaphragm. Amongst these preconceptions is that of the "relative immobility" of the central or cordiform tendon of the diaphragm. On the solitary occasion in which Dr Knott had an opportunity of studying the movements of the diaphragm by the aid of the x rays he would have found had he fixed the screen and divided it into inch squares, that it was he and not the "accomplished physicist' that was deceived by the movements of the ribs If he will take the trouble to examine the first ten subjects that come to hand he will find that the movements of the middle and lateral leaflets of the diaphragm correspond to the measurements given in my lecture. The experience will also convince Dr Knott that it is a dangerous thing to generalise from a rough guess made on a single instance.

Dr Knott cites the phenomena to be seen in a hiccoughing boy as irrefutable evidence of the relative immobility of the central tendon of the diaphragm. I followed minutely his directions for the production of hiccoughing as regards boy, bribe, and oatmeal, but failed to produce it in any one of the six individuals investigated. Whether the failure was due to the inhibition of expectancy or to some further error of observation on the part of Dr Knott I cannot say There can be no doubt, however, that he is perfectly right in asserting that in *hiccoughing* the central part of the diaphragm is relatively immobile although he is apparently quite unaware of the cause of the immobility At the commencement of a hiccough, as may be seen in the illuminated body, all the muscular fibres of the diaphragm, both costal and spinal, suddenly contract and attempt to jerk the central tendon downwards. Its descent is arrested and it remains locked by the sudden closure of the glottis When the glottis is opened the central tendon again resumes its ordinary respiratory mobility I am indebted to Dr Knott for calling my attention to the phenomena of hiccoughing, for it provides another instance of the accuracy of my "preposterous explanation" of the action of the diaphragm On inspiration the diaphragm expends its force in three directions (1) in pushing the abdominal viscera forwards and downwards, (2) in drawing the viscera of the thorax in corresponding directions, (3) in raising the abdominal ends of the lower six pairs of ribs (with the exception of the twelfth) In normal respiration the diaphragm assists the external intercostals in elevating the costal margin, but if, as in hiccoughing, the thoracic and abdominal viscera are rendered immoveable, the force of the diaphragm is spent, as Dr Knott so clearly demonstrates, in drawing the abdominal ends of the lower ribs upwards and inwards—that is to say, the diaphragm draws its moveable costal insertion towards its firm spinal margin, a movement which Dr Knott says is impossible to understand

---

[1] THE LANCET Feb 7th p 394

In dealing with the cause of the variability in the position of the diaphragm in dead subjects I inferred that the diaphragm after death represented the phase of complete expiration. To that inference Dr Knott apparently takes no exception, but my statement that "the elasticity of the lungs draws the diaphragm up as far as it will yield" appears to him "in the present state of physical and anatomical knowledge to read rather funny" "It is unnecessary,' he proceeds, "of course, to point out that the lungs, or their elasticity, have no *direct* connexion with the diaphragm" Thereupon Dr Knott makes certain observations on the standard of physiological knowledge he would require of tyros and rapidly becomes mathematical. Now when a man, in dealing with some simple problem in physiology or natural history, becomes mathematical it will be found that in nine cases out of ten, he is trying to prove the existence of something that is not, and to this rule my critic is no exception. I need not quote for Dr Knott that the elasticity of the lungs after death, if modern text-books on physiology are trustworthy, is enough to support a column of mercury from two to five millimetres high, I would rather beg him to leave his study chair for the post-mortem room and to verify certain experiments which I have carried out there for his benefit The experiments are designed to show that the elasticity of the lungs have a great deal to do with the position of the diaphragm. In five subjects varying in age from six months to 52 years the trachea was connected with a manometer In each case there were no pleuritic adhesions Three long hat-pins were inserted in a row perpendicular to the surface of the chest, one with its point buried in the viscera of the right dome, one in the left dome, and one in the middle inserted only in a costal cartilage so as to serve as an index of the movements of the other two when the chest was opened. Dr Knott knows as well as I do that the very partial collapse of the lung which follows an incision in the walls of the thorax was not due to atmospheric pressure, for on opening the chest the pressure is then the same on both surfaces of the lung, but is due entirely to its elasticity The only factor annihilated by opening the chest is the elasticity of the lung In the five cases I measured the elasticity varied from 0 5 to 3 Hg mm As the lungs collapsed and their elastic traction disappeared the domes of the diaphragm and the abdominal viscera within them descended from two to five millimetres. The degree of descent roughly corresponds with the amount of pulmonary elasticity Perhaps when Dr Knott comes to repeat those experiments the idea of the elasticity of the lungs having something to do with the position of the diaphragm may strike him as less "funny" than it did

My description of the diaphragm as a fan shaped digastric muscle, rising from the upper lumbar region of the spine and inserted on the abdominal ends of the lower six ribs appears to Dr Knott a "preposterous" and "physico-metaphysical statement." The statement will strike him in quite a different sense when he becomes better acquainted with the origin, nature, structure, and action of the diaphragm If he approves of the name "digastric" for the muscle which goes by that designation in the neck he cannot legitimately withhold it from the diaphragm, for in nature, in origin, in manner of developement and in action these two muscles correspond point for point.

I have tried to show Dr Knott that "preposterous" is a dangerous word to employ, its use denotes ignorance more frequently than knowledge.

THE VIRCHOW MEMORIAL

To the Editors of THE LANCET

SIRS,—Allow me to inform your readers that the subscription list for the Virchow memorial will close at the end of the present month. So far, 97 subscribers have contributed £225 1*s* 6*d* Further contributions should be sent before Feb 28th to the honorary treasurer of the Virchow Memorial, care of Messrs Robarts, Lubbock, and Co, 15, Lombard street, London, E C

I am, Sirs, yours faithfully,
FELIX SEMON,
Wimpole-street, W Feb 16th 1903 Honorary Secretary

A QUESTION IN INEBRIETY

To the Editors of THE LANCET

SIRS,—In our dealings with inebriates it is an interesting question for us to consider whether we have really to deal with a class of individuals whose will power is a weak or a strong feature of their minds The accepted belief is that the inebriate is a weak willed creature, but a good deal of experience of inebriates has led me to doubt that idea and rather to believe that which I consider to be a fact—i e., that the inebriate is possessed of a will which over rides the other faculties of his mind in so far at least as his appreciation of his moral obligations is concerned, and therefore that his will is the strongest feature in his mind

From a psychological standpoint we may admit that when the will and the other faculties of the mind act in unison we have as the result a properly balanced intellect In the inebriate we frequently observe these other faculties of the mind tending towards a high class of intellect, the latter form being, indeed, often fully revealed together with the tendency to inebriety Should, however, those other faculties of the mind outrun the will to any great extent coördination of the whole is lost and the reasoning powers justify to the mind acts and conceptions which the will is unable to restrain within recognised proper bounds and those aberrations of intellect occur which cause eccentricity and lunacy On the other hand, should the will override these other faculties of the mind the balance again becomes lost and the inebriate the spendthrift, the fanatic *et hoc genus omne* stalk in. We hear constantly of the inebriate who is desirous of giving up drink but that "his will is too weak." It really is that his will is too strong, his will to drink entirely outstrips those other faculties of his mind which present to him his moral obligations not to drink, the result being that such individual s act is the outcome of a major force of will and not that of a minor quantity of it It is in this light, therefore, that I consider that the inebriate is possessed of an unfortunately strong willed temperament and not, as generally accepted, a weak willed one. I would be glad of the views of some of your readers as to this heterodox opinion which I beg to submit to you.

I am, Sirs, yours faithfully

THE LARGE INTESTINE AS AN INTERMITTENT SYPHON

To the Editors of THE LANCET

SIRS,—The publication of my paper on this subject has aroused so much interest that I should like to solicit the coöperation of your readers in helping me with some side issues and I am encouraged to do so by the signal success that has followed a similar attempt,

In the notes which I added to the reprint of the article in the *Edinburgh Medical Journal* and again in the address an abstract of which appeared in THE LANCET of Feb 7th, p 374, I proved as far as could be done by reasoning that the longitudinal bands of the large intestine are normally in a state of continuous tonic contraction. But, having no facilities for observation, I wrote to Dr T G Brodie, of the Examination Hall physiological laboratories, and requested him to look out for this phenomenon I received his answer on Jan. 31st and his conclusion was expressed in these words "I think there is no question whatever but that the longitudinal bands of the colon are tonically contracted" his tonic contraction with its concurrent shortening would e quite enough to produce the rigidity necessary for syphon ction, and it cannot be denied that the large intestine with ts short ascending and long descending tube fulfils in other espects the conditions of a syphon

One of my points was that, on completely filling the olon by injection from the cut ileum, the 20 inch ransverse colon leaves its nine inch bed and becomes longated and tortuous, the same thing must happen in igmoid obstruction. Thus the question arises Is the V shaped colon sometimes a post-mortem change? When a erson is found dead in a sitting position, therefore, should like the maker of the necropsy to notice whether the transverse colon has dropped from its sual site If empty perhaps this could not be expected. Again, I have a suspicion that the constipation and colic of lead poisoning are due to paralysis of the longitudinal bands with the consequent elongation, kinking, and loss of rigidity of the bowel This should not be very difficult to determine Further, since I have shown that hydraulic power is a factor in the propulsion of the intestinal contents, I should like to know with what average force the stream from the ileum enters the cæcum

THE UNIVERSITY OF LONDON AND THE ENGLISH ROYAL COLLEGES OF PHYSICIANS AND SURGEONS

To the Editors of The Lancet

Sirs,—I would like to make a few remarks upon "Africander's" letter in The Lancet of Feb 7th, p 399 He states that "Hitherto the whole crux of the question has been taken to be not a matter of personal ability but of opportunity," and I quite agree with him I contend that opportunity should exist in London, as in other university towns It seems anomalous that out of 60 entries at a London hospital only four should contemplate taking a degree. I submit that out of the same number of students entering, say, at Edinburgh, a very much larger percentage would contemplate and, as a matter of fact, take the degree Further, however judicial the mind of South Africa is in respect to the practitioner of medicine (a country by the bye just now perturbed by political and racial hatred), there is I submit a very great advantage in possessing a degree in the old country, and the opportunity to obtain the same in London would be forthcoming were the Royal Colleges to join the University for examination purposes under the Act of Parliament which contemplated the possible desirability of such a union

I am, Sirs, yours faithfully,
Fredk W Collingwood

Devonshire street W Feb 7th 1903

NOTES FROM INDIA

(From our Special Correspondent)

Mr Jonathan Hutchinson's Leprosy Tour —The Jamsetjee Jejeebhoy Native Hospital in Bombay —The Government Grant to the Pasteur Institute at Kasauli —The Plague Epidemic

The advent of Mr Hutchinson to the principal cities of India is announced by letters in the local papers. Besides asking for information and promising to attend meetings Mr Hutchinson gives a *résumé* of his views upon leprosy He holds that the disease is caused by a bacillus which gains access to the body through the stomach, that there is great danger in eating food directly from the hands of a leper that in the majority of grown up lepers the disease is caused by eating badly cured fish, and that a long period is necessary before results will be observed. It remains to be seen how the profession in India will receive these opinions which many consider are advanced on very imperfect scientific data.

The public appeal for money in aid of the nursing establishment of the Jamsetjee Jejeebhoy Native Hospital in Bombay is accompanied by the announcement of an extraordinary condition of the nursing staff Here we have the largest native hospital in Bombay of no less than 460 beds which are always full, with 15 wards totally unnursed and seven others only nursed during the day There is no complaint about the buildings and the staff is for the most part drawn from the Indian Medical Service. Treatment can hardly be conducted with much satisfaction to the medical men and the patients are without one of the main advantages of a hospital It is stated that the Bombay Government is prepared to assist to the extent of half the expenditure necessary

The increase in the Government of India grant to the Pasteur Institute at Kasauli is not marked by excessive liberality Hitherto Rs 9500 have been contributed, but in future Rs. 12,000 have been promised Considering that 119 European and 33 native military patients were treated last year and that if the institute had not been established a very much larger sum than the above would have been incurred in sending British soldiers to Paris, the apparent generosity is in reality a sharp stroke of business. The institute is dependent in part upon private subscriptions and is necessarily hampered in its work by uncertainty in income As other scientific work than the treatment of rabies is conducted at this institute it is of the highest importance that its expenses should be completely covered and Rs 20,000 at least should be the annual grant made from the Government of India alone

Every week now records rapidly rising figures in the plague mortality throughout India. Last week 22,954 deaths were recorded, as compared with 19,231 for the previous seven days and with 11,445 for the corresponding week last year In the Bombay Presidency 10,747 deaths were returned, in Bombay city 495, in the Madras Presidency 848, in the Bengal Presidency 3060, in Calcutta 76, in the United Provinces 2954 in the Punjab 2627, in the Central Provinces 850, in the Hyderabad State 446, and in Berar 596 For some extraordinary reason the Poona figures are not included in the published returns, but local papers show that it is raging in this town with extraordinary virulence, over 100 deaths occurring daily The disease is still severe in Karachi and is also severe in Allahabad, Meerut, Benares, and Lucknow, while the Cawnpore district continues to suffer very badly In Bombay city the rate of mortality is about 90 per 1000 per annum In Calcutta the recrudescence is rapidly developing Madras has shown some indigenous cases and other cases are reported from Simla

The mass of poor humanity which assembled in Calcutta upon the large Maidan to be fed in celebration of the King's Coronation numbered probably 50,000 The wretched physique of the majority of these beggars was painfully evident and the collection offered many opportunities of seeing external diseased conditions Skin diseases were very common, especially the different forms of parasitic origin, and numerous lepers moved amongst the crowd. Deformities paralytic states, and conditions produced by chronic diseases such as malaria and elephantiasis were everywhere evident The Hindu portion consisted largely of professional beggars A few years ago such a gathering would have been condemned as conducive to the spread of plague, but subsequent knowledge has shown that a plague patient would be either too ill to go or not in a stage of contagion.

Jan. 30th

Literary Intelligence —The Scientific Press, Limited, announces the publication of a cheap edition, price 10*s* 6*d* net, of Dr R. Sisley's work, "The London Water-Supply" Messrs W B Saunders and Co announce the immediate publication of two new volumes in 'Saunders's Medical Hand Atlas Series"—viz., "Atlas and Epitome of Diseases of the Mouth, Pharynx, and Nose," by Dr L. Grünwald of Munich, edited, with additions, by Dr J E Newcomb, and Atlas and Epitome of Human Histology and Microscopical Anatomy," by Professor Dr J Sobotta of Würzburg, edited with additions, by Dr G C Huber Messrs. Saunders and Co have in preparation for early publication two new volumes in their English edition of Nothnagel's Practice—viz, 'Diseases of the Pancreas, Suprarenal Capsules and Liver," and 'Diseases of the Stomach' —Mr Henry Frowde announces the approaching publication by the Oxford University Press of Dr A. J Ewart's treatise on "The Physics and Physiology of Protoplasmic Steaming in Plants," of which an abstract was communicated to the Royal Society

(Continued from p 480)

The Swansea Single Men pay for Medical Attendance on the Wives and Children of the Married Men —Figures demonstrate the Charitable Aspect of Club Practice — Complaints against the Medical Officers

IT has been seen that at Swansea the custom is that men only pay for medical aid. Their wives and children have to be attended without the member of the club or society being called upon to make any extra payment on their account. A member who has no wife or child pays the same subscription as the member who has a large family This is a strange and unusual arrangement, but when viewed from the workmen's standpoint it has a beautiful, a poetical, and altruistic appearance Are we not told, they say, to bear each other's burdens? and who can better afford to pay for the *married man's family than the bachelor?* In his turn, if a married man has only two children should he not contribute something for the man who has half a dozen children? With such principles there should be no decrease in the birth rate, but the medical practitioner objects to these theories, however beautiful they may be, when they are not put into practice except at his expense If the bachelors will pay for married men's children, well and good, but then they should pay and not merely talk about it *It is not an average of* 6*s* 6*d* per member that will cover the cost of attending numerous families But the workmen challenge these figures and have tried to demonstrate that the single men pay enough to make up for the acknowledged insufficiency of the payments effected by the married men. One case, for instance, is cited of a married man who pays 6*s* a year to his lodge but has two unmarried sons who subscribe to two other societies, and altogether his household pays about £1 13*s* 4*d* per annum It is obvious that no argument can be based on such a case as this. No one desires that any individual family should contribute *too* much, but what were the payments of this family before the children had grown up and what will happen when they marry? Again, the workmen say that they often belong to several societies and that they therefore pay for several medical men. This unsatisfactory state of affairs is not, however desired by the members of the profession , they would wish that only one medical man should be engaged but that he should be properly remunerated. Besides, this simply means that the most popular medical man has the *most* work *to do and does not* get proportionate pay Dr John D Davies has calculated that the medical profession is overworked at Swansea He says that there are 44 practitioners in the town and this means, in round numbers the population being 97,000, one practitioner for every 2000 persons At Cardiff there are 113 practitioners and this is equal to one for every 1143 persons and at Newport there is one practitioner for every 1800 of the population To make a decent living from club practice alone at the old Swansea rate of payment it would be necessary, Dr Davies reckons, to see about 100 patients per day and this is not possible short of defrauding the patient and converting the practitioner into a mere machine.

Dr T D Griffiths, who is to preside over the next meeting of the British Medical Association, is of opinion that there should be one medical practitioner for every 1100 persons According to figures derived from the Order of Foresters the average number of members on the club funds at a time amounts to 3 per cent of the total membership So if there are 1100 members this means that there would be an average of 33 patients per day to attend To do such work properly and including the time required to go from house to house it is not possible to see more than four patients per hour and this means 32 patients in a day of eight hours But this calculation under estimates the position, for it is based on the health of members of a friendly society—that is to say, of adult males —and it may well be estimated that for one member who requires medical attendance there are at least two women or children who are also ill. Dr Griffiths makes, however, another calculation He says if 100 members pay 4*s* a year each this yields £20, or £6 13*s* 4*d* for each of the three members who are ill all the year round, and this amounts to 2*s* 6*d* per week for attending a patient. The chief registrar of friendly societies has based the sick pay to be allowed on calculations extending over some millions of members and he concludes that the average amount of sickness equals 12 days per annum per member This confirms the previous estimate, for the 4*s* annual subscription divided by the 12 days of sickness does amount to about 2*s* 6*d* per week for attending the patients. These figures are taken from the statistics of the friendly societies themselves

Though the insufficiency of the pay is thus very clearly demonstrated the members of the friendly societies found it difficult to believe that their medical officers had good cause for dissatisfaction. Why, they urged, was such work accepted and why, when a vacancy occurred, were there so many applicants for the vacant post? At Swansea an answer was made, or was said to have been made, that greatly startled—not to say shocked—the members of the friendly societies It has been admitted that some club medical officers merely gave value for value; in other words, they did not do as much for patients who, on on average, only paid from 3*d* to 6*d* per consultation as they did for those who paid 2*s* 6*d* This frank admission has caused quite a scandal Some local leaders promptly replied that if this was the case they would dismiss all their medical officers, they would amalgamate all their clubs, and found a large medical institute, where they would employ their own medical officers who should be entirely at their service. Furthermore, they would buy their own drugs and thus insure that they should be of the best quality A lengthy circular was issued to this effect It states, among other things —

> That the grievance is that under existing conditions club patients do not get the proper attendance and medicine which they have a right to expect. In saying this we only state what is a well known fact to most friendly society members How often do we hear the complaint from our members as to the indifference and inattention *of doctors to* club patients Is it infrequent that we hear of members protesting that rather than go to a club doctor to whom they pay their contributions ungrudgingly they go to another and pay him fees which in many cases they can ill afford to pay? Why these complaints have become so common that the name of club doctor is a reproach among the members

This is an important statement and perhaps was considered by its author as an attack against the medical profession, but it, on the contrary, confirms the arguments so frequently brought forward in these columns. The circular containing the above passage is addressed to the friendly societies and the opening paragraph explains that—

> In pursuance of a resolution passed at a general meeting of delegates representing the various branches of the friendly societies of Swansea and district held at the lodge room of the Bird in Hand Hotel High street on Friday evening Nov 28th we beg to submit the following for your consideration

The circular is therefore and in its way an official document and it distinctly proclaims what has always been urged in these columns that club practice must inevitably tend to degrade the profession Undoubtedly, patients do not always obtain proper attendance and medicine, but they have only the "right" to expect this on one of two conditions. They must pay for it or else they must be considered fit and proper subjects for the receipt of charity But the members of the friendly societies seek to avoid both these issues , they do not subscribe enough to constitute a payment and yet they are very indignant when told that they are in receipt of charity Nevertheless, the fact remains that whenever a club patient is properly attended he is in receipt of charity, but as medical men cannot spend all their lives and substance in works of charity the complaints made in the circular are sometimes based on fact

Dr Griffiths has explained that when he first commenced to practise at Swansea he took a club and its members paid him 5*s* a year He contracted with a druggist to dispense for him at the average charge of 6*d* per bottle of medicine and 2*d* per box of pills. At the end of his first year Dr Griffiths found that his drug bill exceeded by £11 the amount he had received from the club Was not this charity to the amount of £11 in cash and all the labour of attending the patients? The practical upshot is that to make the 5*s* subscription yield some small remuneration the drug bill must be reduced from an average of 6*d* to about 1*d* per bottle. This club met at the "Adam and Eve" in High street and Dr Griffiths promptly resigned his position as their medical officer He then received a deputation from a club that met at the "Bird in Hand" and had about

500 members He carefully studied the figures they submitted to him as to the number of members and their families he would have to attend and found that the remuneration offered was equal to 1½*d* for each attendance. Therefore if he resigned himself to spending a large portion of his time in dispensing his own medicines and resorted to expedients necessary so as to reduce the average cost of the medicines to 1*d* per bottle, he would receive a net profit of ½*d* for each attendance in payment for his skill and knowledge as a physician and also as a dispenser Yet the men who made Dr Griffiths this munificent offer would deny that they were asking for charity Dr Griffiths has consequently and publicly proclaimed that he preferred to give up the clubs. He has urged that no respectable man could accept such conditions and that if those who did accept such terms resorted to disreputable practices the primary blame rested with the clubs which sought to sweat the profession. As the subscriptions were insufficient to remunerate the medical officer, it would not be surprising if various stratagems were invented to induce the members to order or to purchase some special drug or in some other way to incur an outlay not comprised in the terms of the contract. The tendency to push the sale of such extras was inevitable so long as the medical officers were not properly remunerated.

Under such conditions the complaints made in the passage of the circular quoted above are only just what might be expected, but in thus complaining the circular unwittingly acknowledges that the medical officers could be properly remunerated There has never been any objection to attending the genuinely poor for little or nothing The objection is against giving what practically amounts to medical charity to those who can afford to pay, and here we find it acknowledged that the members of the friendly societies not infrequently go to a private practitioner and pay him fees which "in many cases they can ill afford." Therefore the members of the friendly societies can pay the ordinary fees since it is here publicly admitted that they do pay the ordinary fees. This we are told they can ill afford in many cases, therefore they can afford to pay the proper fee in some cases Why, then, do they attempt to avoid doing so? Have we not in this sentence an official acknowledgment made and indorsed by the friendly societies themselves that the complaint of the medical profession is well founded? that there is abuse in the club system and that there are members who can afford to pay the usual fee and who have therefore no right to claim the semi charity if not the absolute charity, associated with the system of contract work?

Nevertheless and immediately after this admission that abuse does exist the circular goes on to quote a letter written to the medical journals by the Registrar of Friendly Societies, saying —

> Do the friendly societies ask for medical relief as a charity? or do they wish to sweat the medical profession, or are they willing to pay a fair price for the services rendered to them by it. I know them well enough to answer the question without hesitation They desire to pay a fair price for the services rendered to them. They are neither beggars or sweaters

The circular commenting on this letter states —

> The friendly societies have always been willing to pay a fair price, but if the price has not been satisfactory to the medical profession in Swansea then they themselves are to blame. The present low rates are due to the undercutting that has been going on amongst themselves for some years past. In spite however of these rates which they consider to be low we know that when a vacancy for a medical officer occurs in a branch that the competition for the vacancy is very keen, and the methods resorted to in order to obtain the office are not, in all cases such as add to the dignity of the medical profession.

This, again, confirms much of what has been said in the course of this series of articles. Many a time have the "undercutting tendencies of certain practitioners been denounced It is to prevent such practices that the organisation of medical unions throughout the country is advocated. As a result of this movement the competition for vacancies in club practice is now not so keen as it was some years ago Indeed, there are cases where it has been impossible to obtain any medical officer to fill a vacant post. Some of the insurance companies which organised medical aid in the same manner as the friendly societies have now abandoned this phase of their business There can be no doubt that progress has been achieved within the last five or six years. Still there are weak kneed members of the profession At the joint meeting of medical representatives and the delegates of the friendly societies at Swansea Mr Lake, secretary of the latter organisations is, according to the shorthand notes taken at the time, reported to have declared that some medical officer had said to the members of the societies, "Never mind, we understand each other, do not trouble," and another said, "I will give you back so much if this increase comes about." At this there were loud cries of "Name," but Mr Lake replied, "No, it is enough for me to say I was in the lodge when the offer was made." It is not surprising if some of the workmen are still under the impression that they pay a sufficient subscription to medical officers of their clubs. Then when they find that they are not attended to with sufficient care or if they suspect the quality of the medicine given they complain that they are being robbed right and left, and that though they subscribe to a club medical officer they are constantly compelled to seek the advice of a private practitioner There is in this a rough justice which it would be to the material advantage of the friendly societies to take into more serious consideration If such complaints are well founded—and it is generally admitted that there is some truth in them—what would be the consequence? Simply that patients would remain longer on the sick list and therefore draw larger sums as sick allowance. Consequently the drain on the societies' funds for sick pay is likely to exceed the sum necessary to remunerate sufficiently their medical officer The attitude of the friendly societies is that they give insufficient remuneration to their medical officers and trust that, in defence of the honour of their profession, the medical officers will nevertheless give back in exchange sufficient and efficient attendance and medicine. It sometimes happens, however, that the medical officer adopts the commercial rather than the professional point of view and therefore returns tit for tat and only gives his patients their money's worth. Then there are sounds of lamentation the medical officer's behaviour is denounced as most scandalous, and the friendly societies make big threats of discharging all the medical officers and founding a medical institute solely under the control of the friendly societies

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT)

Royal Southern Hospital Grave Financial Situation.

THE sixty first annual report of the working of the Royal Southern Hospital states that the balance due to the bank had now reached the high figure of £5601. The number of patients treated during the year was 13 355, of which 2431 were in patients, the number of attendances was 47 103, making a total of 60 458 and showing a considerable increase on previous years. The services of the horse ambulance were called for in 458 emergencies. The average number of beds occupied was 192. The number of cases in the tropical diseases ward was 137 as compared with 131 last year Dr W Permewan, in seconding a vote of thanks to the Lord Mayor for presiding at the annual meeting, said that the time would come before long when the city would not only feel it its duty but its plain interest to keep up and to maintain an efficient system of hospitals. It was now by a recent decision of the Local Government Board, within the power of the corporation to establish and to maintain a hospital for any purpose and not only for the treatment of infectious diseases as was generally supposed. The Lord Mayor, in replying to the vote of thanks, endorsed Dr Permewan's remarks on corporation hospital management and said that the time would probably come when some of the hospitals would be taken over by the city and placed entirely on the rates. His lordship suggested that probably those responsible for the administrative departments of the several hospitals of the city might learn something from each other by conferring upon the best methods of reducing the cost per head of the patients in the hospitals In the Royal Southern Hospital the cost per head was under £50 per annum

Small-pox in Liverpool Slight Abatement in the Number of Reported Cases the Tramp Nuisance

There were 306 patients suffering from small pox in the corporation hospitals on Feb 12th Only 45 fresh cases were reported during the week, as against 131 during the previous week. The spread of the disease is largely due in

Liverpool to tramps Dr E W Hope, the medical officer of health, is of the opinion that they leave a trail of disease behind them. There is a class of idle loafers who alternate between the gaol and the tramp sheds of the workhouses and wherever they go they are a nuisance. A letter from the Local Government Board bearing on this subject will shortly be laid before the health committee. Nothing has been more clearly proved than that the dissemination of small pox has been very largely owing to tramps Stringent measures have been taken to deal with them in Liverpool. More drastic measures generally in dealing with this class of pest (in Dr Hope's opinion) would prevent a great many outbreaks of the disease

The Liverpool Cancer Research Fund in connexion with University College and the Royal Infirmary

The director of the Liverpool Cancer Research (Sutton Timmis) Fund, Dr A. S F Grünbaum, has issued a circular letter to the local members of the medical profession in which he states that the objects of the foundation are (1) to investigate the biology and chemistry of the disease, (2) to attempt the production of curative remedies, (3) to discover, if possible, means for the prevention of the occurrence and spread of the disease, and (4) to investigate, experimentally and otherwise, the questions of etiology relating to heredity, locality, occupation, &c Dr Grünbaum appeals to his professional brethren to give him the opportunity of obtaining fresh specimens of malignant tumours when occasion presents itself.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

The New Professor of Anatomy in the University of Edinburgh

THE curators of patronage of the University of Edinburgh met last week for the purpose of considering the vacancy in the chair of anatomy created by the promotion of Sir William Turner to be Principal. The curators having learned that Dr D J Cunningham, professor of anatomy in Trinity College, Dublin, was willing to accept the Edinburgh chair, unanimously decided that in view of his pre eminent qualifications it was unnecessary to consider other applications and that he should be invited to succeed Sir William Turner The appointment of Professor Cunningham had been anticipated, so that the intimation did not cause any surprise. The manner in which the appointment has been made may well be highly gratifying to Professor Cunningham. I do not remember any other appointment to a medical chair being made in this way Professor Cunningham will be warmly welcomed back to Edinburgh, where many men who knew him in student days now occupy prominent positions Professor Cunningham graduated in medicine at the University of Edinburgh in 1874 with first-class honours. Two years later he took the degree of M D, receiving a gold medal for his thesis on the Anatomy of the Cetacea. In 1876 he became senior demonstrator of anatomy in the university under Sir William (then Dr) Turner and this position he held for six years, when he received his appointment at Dublin. Professor Cunningham has been a fruitful contributor to anatomical science and his scientific attainments have been recognised by the conferring upon him of honorary degrees by the Universities of Dublin, Oxford, Glasgow, and St. Andrews

Carnegie Trust Scheme for Post Graduate Study and Research

The executive committee of this trust has published its regulations for scholarships fellowships, and grants. The scholarships are intended to afford promising graduates an opportunity of training and proving their powers in higher study and research, and may in this way qualify scholars for fellowships Each scholar is selected by the trustees on nomination by a professor or lecturer, but the trustees in considering a nomination may include the opinions of others also who are acquainted with his qualifications The scholarships are to be of the value of £100 per annum and may be held for two years During the tenure of the scholarship no other scholarship can be held, but in the case of such a scholarship being held the trustees may supplement it so as to bring it up to £100 per annum No position of emolument can be held with a scholarship except with the sanction of the executive committee. Ordinarily a scholar is expected to devote his whole time to the purpose for which the scholarship is awarded. The scholar has to work under the supervision of the professor or lecturer who nominates him. The fellowships are for graduates who have already, preferably by work published, shown their capability of advancing science or medicine and who desire to devote themselves further to this work. These are of the annual value of £150, exclusive of such special expenses in connexion with a research as the executive committee may allow Here, also, no other fellowship or position of emolument is allowed save on the same terms as mentioned above as applicable to the scholars. The fellowships may be held for three years if the executive committee decide so to extend them Finally, the committee will consider applications for grants in aid of research These are open to professors, lecturers, and assistants in Scottish universities, any teacher in Scotland recognised for the purpose of graduation in a Scottish university, or a Scottish university graduate resident in Scotland. The applicant must submit evidence of his experience in research, the nature of the proposed research, the time it will take, and the estimated cost. The executive committee of the Carnegie trust is again to be congratulated on its statesman like grasp of this difficult question and on the very admirable nature of the arrangements it has made. The young men in Scotland seem to me to be given an enviable opportunity of showing their interest in, and capacity for, original work. The scheme conserves, as it was bound to do, the interest of university graduates while allowing considerable choice as to the laboratory in which research can be pursued.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Zymotic Health of Dublin

AT the last meeting of the managing committee of Cork street Fever Hospital, the registrar reported that the number of recent admissions was unusually high There was a local outbreak of typhus fever in the city which resulted in the admission of many cases of that disease, while many patients with scarlet fever and others with diphtheria of a severe type were received during the two weeks ending on Feb 12th

County Monaghan Infirmary

From the statement of accounts for the year ending Jan 5th, 1903, it appears that there is a balance of £496 12*s* 3*d* to the credit of this institution. There is an increase of £200 as compared with the previous year The Local Government Board has instructed one of its medical inspectors to visit the infirmary and to report as to its recognition as a school for the training of medical and surgical nurses

The Ulster Medical Society

The President of the Ulster Medical Society (Dr John Campbell) entertained the members of that association at a smoking concert in the Medical Institute, Belfast, on Feb 12th, when there was a large attendance. Refreshments were served at one end of the main lecture hall and during the evening an admirable programme of recitations and musical (vocal and instrumental) items were given The concert was in every respect a great success.

The Samaritan Hospital, Belfast

At the annual meeting of the supporters of the Belfast Samaritan Hospital held on Feb 16th it was reported that during the past year 536 extern and 149 intern patients were treated Of the latter 115 required surgical aid There were 25 major operations. Owing to loss of subscriptions the income is less than last year, so that there is a balance due to the bank of £250 Owing to a case of typhoid fever occurring among the nursing staff it was decided to overhaul the drains after the patient's recovery, this was done at great expense and practically led to a closing of the wards for the last quarter of the year To put the finances in a satisfactory condition 100 additional subscribers of £1 and 50 additional ones of 10*s* are needed It is hoped in the interests of this excellent institution that this financial help will be secured.

(FROM OUR OWN CORRESPONDENT)

The Alcohol Question

THE alcohol question is being fought out with vigour on both sides. The Distillers and Alcohol Sellers' Union, not content with having brought an action against the Prefect of the Seine and the Director of the Assistance Publique for having placarded Paris with anti alcohol notices signed in their joint names, has now had a meeting of its members. These members have determined to placard every town in France with a counterblast to the effect that alcohol is not a poison but a useful food, giving as their authority M. Duclaux, whose opinion I quoted in THE LANCET of Feb 7th At the meeting of the Academy of Medicine which was held on Feb 3rd M. Laborde said that he wished to protest in the strongest fashion against the opinion of M. Duclaux. Alcohol, said M. Laborde, is not a food—it is a drug, one which stimulates for a moment but which exacts a heavy payment afterwards But it is above all things a poison, slow and perfidious it may be in action, but nevertheless sure and far reaching in its effects, for these effects extend even to the progeny of the drinker As for arguing that the common sense of the people will prevent them from abusing alcohol, such argument was a dangerous illusion. After listening to M. Laborde's burning words the Academy heard other speakers who wished some modifications to be made in the report read by M. Laborde at the previous meeting of the Academy This report, which grew out of a Parliamentary question,[1] dealt with the sale of alcoholic drinks containing essential oils. These liquors were to be divided into two classes. Those in the one class were absolutely prohibited and such were liquors containing the natural or synthetic essences of absinthe, star anise (*badiane*), bitter almonds, and the like The other class contained liquors which were only to be sold under the most stringent regulations and included those containing essence of mint, melissa, arnica, nutmeg, sandal wood, sage, and others, including the residual alkaloids of cinchona. M Hanriot thought that the chief point to be observed was that the alcohol should be pure. Alcohol, he argued, is the substratum of all alcoholic drinks and the flavouring essence simply added its poisonous quality The higher alcohols should be absolutely forbidden because of their poisonous qualities Methylic alcohol only existed in a liquor as an impurity or an adulterant and therefore all liquors containing it ought to be rejected. The various flavouring agents should be dealt with individually according to their various grades of toxicity Essence of bitter almonds was only moderately poisonous and it would be therefore better not to proscribe it absolutely for fear of driving drinkers to consume other and more poisonous essences. M. Hanriot proposed that the manufacture and sale of every liquor containing essence of absinthe or hydrocyanic acid in a greater proportion than that of a decigramme to a litre should be absolutely forbidden M. Daremberg said that essence of anise being more poisonous than essence of star anise should be prohibited Essence of juniper was not poisonous M Bouchard thought that the essences of anise, of star anise, and of fennel should all be put in the same class. The manufacturers purify these by crystallisation and obtain a product which contains 90 per cent. of anethol The forbidding of the sale of essence of absinthe was an illusory precaution for the absinthine contained therein could be obtained from other essences. M. Raymond gave some statistics of 2000 patients observed by him in the Salpêtrière during the year 1902 to 1903. Of these patients both men and women, 66 per cent. were alcoholics Of the whole number 10 per cent were markedly alcoholic and bore evident signs of intoxication. Alcohol favoured the development of both tabes dorsalis and epilepsy M Raymond quoted the case of a woman in whom epilepsy developed in a very marked manner after absinthe poisoning and of another who exhibited a polyneuritis after intoxication by *eau de melisse*

The Funded Property of the General Association of French Medical Men

There is at present great excitement among the members of the council of the above mentioned association. This benevolent society possesses considerable funded property which in accordance with the law is invested in a public institution called the "Caisse des Dépôts et Consignations," which pays out interest on the money Out of this interest are paid pensions to those members of the association who have fallen on evil days or to their widows By a law dated April 1st, 1898, the rate of interest was fixed at 3½ per cent., but by special arrangement it may be as much as 4½ per cent. The director of the Caisse des Dépôts et Consignations has, however, just transferred the capital of the association to a different schedule by which the interest allowed is only at the rate of 1½ per cent. This stroke of business, which at once reduces the resources of the association by some two-thirds, has naturally enough brought about vigorous opposition from the council. A deputation has been appointed to wait on the Minister of the Interior who is himself much surprised at the arbitrary action of the director of the Caisse The Minister himself wrote a letter to this official who, however, refused to modify his decision alleging that his action was in accordance with instructions received from his council. The association has therefore brought an action against the director so that the matter will be submitted for judgment to the Conseil d'État. The association is besides in trouble in other ways. The general secretary of the association, M Lereboullet, and Dr Lande have together formulated the idea of publishing a great medical journal, the expenses to be paid by the association and the journal to be distributed gratuitously to all its members. As these members include nearly half of the whole of the medical profession this idea if carried out would mean the stopping of practically the whole of the rest of the medical press of France. The syndicate of the medical press has therefore held an extraordinary meeting and has decided that if the association should carry out its idea an action should be brought against it for having violated the first article of the law dealing with friendly societies, which states that such societies should not engage in any commercial transaction. The association hopes to pay the expenses of its journal by money received for advertisements which would constitute a commercial transaction.

The Waters of Luchon

At the meeting of the Academy of Medicine held on Feb 3rd M Moissan stated that from an examination of the Grotto spring at Luchon he was able to affirm that the sulphur in the water at the springhead was in the form of sodium monosulphide. In the inhalation rooms, however the sulphur existed as sulphur vapourised at a temperature of 50° C and not as sulphuretted hydrogen Moreover, the staff of the inhalation rooms who work there for some six months of the year never show any of the symptoms which even slight doses of sulphuretted hydrogen bring about. M. Berthelot agreed with M Moissan and said that sulphur gives off no vapours at ordinary temperatures, but at a temperature of 50° C the vapour has a sensible tension If the water is at a higher temperature it holds the sulphur which will settle out on cooling as sulphur Workers in vineyards who sulphur the vines know well that sulphured vines give off sulphur vapours under a hot sun M. Armand Gautier added that sulphur waters introduce sulphur into the economy in some way not at all clearly understood He had experimented upon himself and had been unable to detect either sulphuretted hydrogen or sulphur on his skin after a bath.

The Treatment of Incurable Cases of Tuberculosis

An interesting experiment is about to be made on behalf of incurable cases of tuberculosis The council of the Assistance Publique has decided to set on foot a special department, annexed to a Paris hospital for the care of advanced cases of tuberculosis. The Pitié Hospital is the one selected and the cases will be placed in charge of M. Robin M Mesureur the director of the Assistance Publique is arranging with the director of the hospital as to a site for the wards for tuberculosis The wards will contain 26 beds

BERLIN

(FROM OUR OWN CORRESPONDENT)

Specialism in Medicine and Surgery

PARAGRAPHS have recently appeared in the newspapers to the effect that the Government intends to introduce legislation relative to medical and surgical specialists, and it has been definitely stated that not long ago, at a meeting of the Prussian medical chambers, Dr Kirchner, a member of the Government medical department, announced that a Bill would be brought in requiring an additional examination to be passed by those medical men who desired to have the title of specialist granted to them. The news caused some surprise and the project was from the first regarded by the medical profession with disapproval. It was argued that in the event of an additional qualification for specialists being made compulsory only those medical men would be admitted to the examination who had worked in a public clinic such as that of a university and that the necessary certificates for the examination would be obtainable only from such clinics. It is well known that many specialists, including some of the most competent, have begun to work in their special branch after having been engaged in general practice, others have received their training either in private clinics or by becoming assistants to established specialists or by attending lectures and courses of instruction either in Germany or elsewhere It is true that this system has occasionally led to abuses, for some medical men have been known to put themselves forward as specialists after having attended courses of instruction in their particular branch for only a few weeks These worthies, who were familiarly known in the profession as "six weeks' specialists," hardly ever prospered in their new departure, and either very soon returned to general practice or else endeavoured to extend their knowledge by further study This abuse has not, however, at any time attained proportions sufficient to justify such a radical measure as compelling specialists to take an additional qualification, and the unanimous disapproval of the medical profession has apparently had the effect of influencing the Government, for the semi official journals declare that Dr Kirchner's words have been misunderstood and that the Government has no present intention of creating a new qualification for specialists It is furthermore pointed out that the regulations affecting medical qualifications are controlled by the Federal Council and are the same throughout the empire, for which reason an individual state like Prussia could have no power to alter these regulations without the consent of the Imperial authorities The *Berliner Aerzte Correspondenz* announces that it is authorised to deny all the current rumours relative to the alleged project—a turn of affairs which will commend itself to those who disapprove of too much Government interference in medical questions

---

[1] THE LANCET July 15th 1902, p. 49

Health of the Army

According to a report issued by the Army Medical Department and quoted by the *Deutsche Medicinische Wochenschrift* the invaliding during the period from Oct. 1st, 1898, to Sept. 30th, 1899, was 355 446 out of an effective force of 514,569 men, or a proportion of 690·8 per 1000, as compared with 682·5 per 1000 during the previous twelve months The mortality continues to decrease, being only 2·1 per 1000 during the period in question, whereas the average for the period from 1881 to 1886 was 4·1 per 1000 Of the men invalided during the twelve months 1898–99 the proportion who returned to duty was 924·1 per 1000, 783, or 2·1 per 1000, died, of whom 13, or 0·04 per 1000, committed suicide, and 6661 were discharged as unfit for service In about one third of all the cases the causes of complete invaliding were diseases of the respiratory organs About 1600 men were sent for treatment at spas and watering places at the public expense. Infectious diseases showed a relatively considerable increase—namely, 34·6 per 1000, as compared with 24·3 per 1000 in the previous twelve-month. This increase was principally due to the prevalence of influenza, enteric fever, diphtheria, venereal diseases, and tuberculosis, on the other hand showed a diminution. The report, which is very comprehensive as well as instructive, deals also with the military hospitals In five garrisons new hospitals were established and in seven the existing buildings were enlarged and improved. Several hospitals have been provided with new operating rooms and supplied with apparatus for Roentgen ray work and for the application of mechanical movements in medical treatment. With respect to food, it is mentioned that trials which had been made of frozen meat had been very successful, it could be conveyed long distances in the height of summer without sustaining damage.

The Battle of the Clubs

Some alterations are to be made in the laws relative to the workmen's clubs which insure against sickness. According to a Bill which is at present under discussion by the Federal Council the sick clubs will have to support their members for 26 weeks instead of for 13 weeks, as required by the existing law, and women will have to be supported for six weeks after confinement instead of for four weeks as at present. It is also a great improvement that the objectionable exclusion from the benefits of the club which is at present imposed on members suffering from venereal diseases will be abolished and that these members will be entitled to the same rights as any other patients The Bill, however, does not contain any provision relative either to the insurance of the families of members or to the position of the medical officers of the clubs. Considering the immediate interest of the medical profession in questions connected with these clubs it is remarkable that the official representatives of the profession have not been consulted in any way The precarious position of medical officers to sick clubs is only too well known, but if proof is needed it can be supplied by the events leading up to the medical strike which is now in progress at Gera, a manufacturing town about 35 miles from Leipsic. Some years ago medical strikes were not very uncommon in Germany[1] and they have, in fact, ceased to be regarded as sensational, so that the daily newspapers which formerly published long telegrams from Leipsic with details of the strike which took place there now make very little reference to the strike at Gera There is a sick club in that town and the cause of the present dispute was that the committee of the club, contrary to a previous agreement, appointed a so-called "Naturarzt"—i.e., a hydropathist—without regarding the wishes of the other medical officers whose income was affected by the high fees of the "Naturarzt." Of the 33 medical officers 28 at once went on strike and were aided by other medical unions, especially by the Leipziger Verband. This union, consisting of medical men engaged in club practice throughout Germany, was founded after the strike at Leipsic and has collected a considerable fund for the purpose of supporting medical men who had come into difficulties with a club The Leipziger Verband inserted advertisements in all the leading newspapers, medical and non medical, warning medical men against accepting appointments in Gera, and it is reported that in consequence of the steps taken by the union the club finds itself unable to procure medical officers even at higher salaries than before. There is thus reason to hope that the movement will be successful and that the medical officers will compel attention to their remonstrances.

Feb 16th

SWITZERLAND

(FROM OUR OWN CORRESPONDENT)

Treatment of Cholelithiasis

CONSIDERABLE interest has of late been aroused in Switzerland in connexion with the results of new methods of dealing with cholelithiasis introduced by Dr Robert Blaser of Muri, canton Aargau. He has published reports of about 100 cases treated with such great success that he can describe 79 cases as cured, and this restoration to health, according to his statistics, seems to have continued for at least one year 16 cases were improved and six were unimproved. He treated 73 women and 27 men, and diagnosed cholecystitis 39 times, sudden impermeability of the common bile-duct 13 times, and chronic impermeability of it 43 times. He does not consider patients to be cured till they can take ordinary food of a light description. He recommends that cases of gall stone should be treated medicinally, if possible, for from four to six weeks in a sanatorium and then at home for a couple of months, and he maintains that by this system they will often be spared the necessity of a course of treatment at Carlsbad and operative interference. He is of opinion that his treatment increases the amount of biliary salts and the total amount of bile and that it dissolves cholesterin, therefore slowly dissolving gall stones and acting in a directly curative manner He has, after an experience extending over a period of 12 years, combined the following remedies hydrargyrum in small doses (not more than one-sixth of a grain per diem), podophyllin, oil of peppermint, melissa, and aniseed In cases of acute biliary colic a bandage soaked with a mixture of poppy seed oil and chloroform always gave immediate relief, so that he never had to resort to morphine injections. It is most desirable that the patients should be under careful medical supervision at a sanatorium for at least one month, so as to be free from work and worry

---

[1] THE LANCET April 27th 1901 p 1242.

He insists (1) on frequent deep inspirations to increase the flow of bile and to improve the circulation , and (2) on plenty of fresh air with a maximum amount of exercise. He gives his patients a mixed dietary with meat and vegetables, avoids raw fruit and some sorts of fish, such as salmon, and especially insists on careful mastication and slow eating He orders saline baths containing carbon dioxide, as at Nauheim. He considers cholelithiasis to be primarily a nervous disease —a disorder of the branches passing from the vagus and sympathetic to the liver The bile is thereby rendered abnormal, cholesterin is formed, the bile becomes infected, catarrh ensues, bilirubin is excreted, a calculus either partially or totally hinders the exit of the bile from the gall bladder, and local hyperæsthesia becomes established It may not be possible to follow Dr Blaser in all these hypotheses, but his practical results are such that many medical men will probably be disposed to try this new method of treatment before recommending surgical intervention for their patients suffering from biliary colic.

Zürich Feb 16th

Obituary.

JOHN ORTON, M.R C S ENG , L.S A.

MR. JOHN ORTON, who died recently at his residence, Foleshill, near Coventry, was one of the best known medical practitioners in North Warwickshire. His professional training was received at the Birmingham General Hospital and in 1867 he took the diploma of M R C S Eng , in the following year he was admitted L S A. He then settled in Foleshill, where his father had previously been in practice, and in course of time he obtained several local appointments, such as those of medical officer of health of Foleshill rural district, medical officer of a Poor law district, and workhouse medical officer For several years Mr Orton took an active interest in political questions He had been in failing health for a considerable period and at the time of his death he was in his fifty ninth year He has left three sons and a daughter one of his sons being Dr John O Orton of Foleshill. Mr Edward W Orton, M.R C S Eng , of Bedworth, also in Warwickshire is a brother of the deceased.

UNIVERSITY OF LONDON —At the Intermediate Examination in Medicine, held in January, the following candidates were successful —

Entire Examination

First Division.—Thomas Charles Clare, Birmingham University Colin Clarke, St Bartholomew's Hospital Arthur Donald Griffith King's College George Stanley Morse St. Bartholomew's Hospital John Morgan O Meara, University College Wilfrid James H Pinniger University College Bristol Lilian Trousdale Rowland London (Royal Free Hospital) School of Medicine for Women Albert Salmon London Hospital and Rawdon Augustus Veale Yorkshire College

Second Division —Eustace Henry Adams Guy's Hospital Wilfrid G Attenborough King's College John Stanley Avery University College Bristol Thomas Henry Barton and Richard John Bentley Guy's Hospital Valentine Henry Blake St. George's Hospital Herbert D Clementi Smith St. Bartholomew's Hospital David Kirkpatrick Coutts St Thomas's Hospital Claude Harold Cross St. Bartholomew's Hospital Ivor Jones Davies University College Cardiff, Arthur Sydney Hahn University College Sheffield George Hamilton and Edward Montague Harrison Guy's Hospital Hyman Isaacs University College Cardiff Herbert Stanley Knight and Edward Farmiuer Milton Guy's Hospital Conwy Llewellyn Morgan St Thomas's Hospital Theodore Charles Pocock, Guy's Hospital Norman Bennett Powell, St Bartholomew's Hospital William Percy Purdom Guy's Hospital Ellis James Roberts and Ernest Littleton Sandiland, London Hospital Frederick Augustus Sharpe Guy's Hospital Olive Bertha Smith London (Royal Free Hospital) School of Medicine for Women Edward John Sunnucks University College Archibald Alfred Sutcliff St. Thomas's Hospital Violet Ackroyd Turkhud London (Royal Free Hospital) School of Medicine for Women Herbert Andrew Watney Guy's Hospital Arthur George Wells University College and Frank T H Wood B Sc. Guy's Hospital

Excluding Physiology

First Division.—Mary O Brien London (Royal Free Hospital) School of Medicine for Women

Second Division.—Alec Barber St Bartholomew's Hospital Henry H. Rudolf Bayley Charing Cross Hospital Lilbrooke Frank Cope St. George's Hospital Edward Vincent Dunkley St. Thomas's Hospital Alexander Harold Gifford King's College Llewelyn Llewelyn London Hospital Bessie We'don Symington London (Royal Free Hospital) School of Medicine for Women Alfred Geddes Tressider London Hospital Ruth Helen Western, London (Royal Free Hospital) School of Medicine for Women and David Wilson St Thomas's Hospital.

Physiology only

Second Division —Leonard Christopher Blackstone University College Isaac Reginald Cook Guy's Hospital, Reginald John Hands Cox and John Harmer Drew St. Thomas's Hospital Guy Stanley Earl, St George's Hospital Harold Oscar Gough, University College Bristol Alfred Wyat Hooker St Thomas's Hospital Frank Douglas Roberts London Hospital and Harold Sugden Vivian Middlesex Hospital

N.B —The foregoing list, published for the convenience of candidates is provisional only and is not final until the report of the examiners shall have been confirmed by the Senate.

UNIVERSITY OF CAMBRIDGE —At the Congregation on Feb 12th the following medical degrees were conferred —

M.B —H. C Williams Pembroke E B Leech Christ's and A F Elliott Emmanuel

B C —H. Davies-Colley Trinity and T StC Smith Trinity Hall.

The Rev E S Roberts, for many years Tutor of Gonville and Caius College, was elected Master on Feb 16th, in the room of the late Dr Ferrers.

TRINITY COLLEGE, DUBLIN —At examinations held recently the following candidates were successful —

Final Examination in Surgery —Seaton S Pringle, Thomas L Sands Demetrius Jacovides Joseph Wallace James T M Entire, William Wiley Thomas Ff Manning Edward V Collen, and John F Nicholson

Section A —James G Wallace John Cunningham Arthur A. M Neight Keith R C Hallowes Wright Mitchell, John A. Sibthorpe, John H Waterhouse George B M Caul, Robert Magill James H. Thompson John Chambre Charles E Fawcett William Hassard Cecil A. Boyd and Francis S Crean

FOREIGN UNIVERSITY INTELLIGENCE — *Berlin* Dr Max Lewandowsky and Dr Friedrich Umber have been recognised as *privat docenten* of Physiology and Internal Medicine respectively —*Berne* Dr Howald has been appointed to the chair of Forensic Medicine —*Breslau* Dr Arthur Dienst has been recognised as *privat docent* of Midwifery and Gynæcology —*Erlangen* Dr Hermann Merkel has been recognised as *privat docent* of Forensic Medicine.—*Gratz* The title of Extraordinary Professor has been granted to Dr Adolf Tobeitz, *privat docent* of Children's Diseases.—*Kieff* Dr Volkovich has been appointed to the chair of Clinical Surgery in succession to Dr Bornhaupt.—*Marburg* Dr Ludwig Aschoff of Göttingen has been appointed to the chair of Pathological Anatomy and General Pathology in succession to Professor Ribbert.—*Moscow* Dr Flëroff has been recognised as *privat docent* of Medicine, Dr N Bazhënoff as *privat docent* of Neurology and Psychiatry and Dr A Starkoff as *privat docent* of Surgery —*Naples* Dr Giuseppe Boccardi Extraordinary Professor of Histology, has been promoted to the Ordinary Professorship Dr Giuseppe Trotta has been recognised as *privat docent* of Midwifery and Gynæcology —*Prague* (*German University*) Professor Von Franqué of Würzburg has been appointed Professor of Midwifery in succession to the late Professor Max Sänger —*Strasburg* Dr H. Jäger of Königsberg has been appointed Extraordinary Professor of Hygiene.—*Vienna* Dr G Nobl has been recognised as *privat docent* of Dermatology

THE LATE N C HATHERLY, M D ABERD, M R C S ENG, STAFF SURGEON R.N (RETIRED) —The funeral took place at South Molton, Devon, on Feb 13th, of Staff Surgeon Narcissus Collins Hatherly, who died on Feb 10th in his eightieth year The deceased was formerly a surgeon in the Royal Navy and for ten years—from 1852 to 1862—was senior assistant surgeon at the Royal Naval Hospital, Plymouth. Staff Surgeon Hatherly was one of the oldest and most esteemed residents of South Molton and had been identified with practically all the works of philanthropy in the town. It was only quite recently that his portrait and an album containing the names of the subscribers were presented to him The funeral was attended by a large number of influential residents and friends Numerous wreaths were sent, amongst those sending them being Earl Fortescue, Viscount Ebrington, and others

SOUTH DEVON AND EAST CORNWALL HOSPITAL —The sixty third annual meeting of the subscribers to this institution was held on Feb 9th under the presidency to the Earl of Mount-Edgcumbe. The medical report stated that during 1902 the in patients numbered 1215 a decrease of 134 as compared with the previous year 3134 out-patients were treated, against 2795 in 1901. 69 nurses and 258 patients were sent to the Pearn Convalescent Home. The financial statement showed that the income amounted to £7415 The expenditure for the year was £8409, leaving a deficit of £994 on the year's working

Health of Bideford Rural District —Mr J H. Hobling in his annual report for 1902 presented at the meeting of the Bideford (Devon) rural district council held on Feb 4th, stated that the population of the district was 6386 The birth rate was 27 1 per 1000 and the death rate was 8 9 per 1000 14 deaths occurred in children under one year of age Mr Hobling considered that several of these were due to ignorance in feeding and at his suggestion the council decided to issue an official leaflet containing instructions as to the feeding of infants and to request the registrar to give copies of it to the parents when the birth of a child was registered.

Bath Eye Infirmary —The annual meeting of the subscribers to this institution was held on Feb 2nd, under the presidency of Mr J S Bartrum. The medical report stated that during 1902 the out-patients numbered 2258, being an increase of 59 as compared with 1901 215 in patients were admitted, against 295 in the previous year The financial statement showed that the total income amounted to £552, and the unfavourable balance of £46 remaining at the end of 1901 had been converted into a balance in hand of £10 , but that in order to effect this the committee had been obliged to reduce the number of the in patients

Parliamentary Intelligence.

THE SESSION OF PARLIAMENT

The session of Parliament was opened by the King on Tuesday Feb 17th with full State ceremony As usual His Majesty's speech gave a forecast of the legislation which the Government proposes to introduce in the course of the session Eleven measures were mentioned including an Education Bill for London a measure amending and consolidating the licensing laws in Scotland a measure for regulating the employment of children and a measure for dealing with the sale of dulterated dairy produce. There was no reference in the speech to he Vaccination Bill but as Mr Chaplin s Act expires at the end of the present year it will no doubt be forthcoming in the course of the session Another notable omission was the Lunacy Bill which year after year has occupied a place in royal speeches It is understood however, that the Lord Chancellor contemplates the introduction of a Bill dealing with the laws as to lunacy

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward it to The Lancet *Office directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week for publication in the next number*

Blake A F M R C S L.R C P Lond., has been appointed Medical Officer for the Grays Division of the Orsett Union

Carr White, Major P M B I M S has been appointed Clinical A sistant to the Samaritan Free Hospital for Women

Clapham Lucy B M.B Lond has been appointed Assistant Anæsthetist to the New Hospital for Women London.

Dismore Henry Bertram L R C P Lond M R.C S has been appointed Medical Officer for the Wroughton District by the Swindon Board of Guardians

Jarvis John M R C S has been appointed Surgeon to the Western Dispensary Bath vice Mr John Davies resigned

Lyell J H. M D C M Glasg has been appointed Outdoor Surgeon to the Royal Infirmary Dundee.

Palmer Harold Lewis M R C S Lond L.S A. Lond J P has been appointed Honorary Consulting Surgeon to the Montgomeryshire Infirmary

Paton E L M.B C M Glasg has been appointed Visiting Surgeon to the Royal Infirmary Dundee.

Pearse, James M.D C M. Edin has been appointed Medical Officer of Health for the Trowbridge (Wilts) Urban District Council

Sandall T E M B B S Cantab has been appointed Certifying Surgeon under the Factory Act for the Alford District of the County of Lincoln

Stirling Robert M D Edin F R C S Eng has been re-appointed Visiting Surgeon to the Royal Infirmary Dundee

Taylor, W M D Edin , has been appointed Visiting Surgeon to the Royal Infirmary Dundee

Wilkins A G M B B S Vict Univ has been appointed Certifying Surgeon under the Factory Act for the Patterdale District of the County of Westmorland.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

Chesterfield and North Derbyshire Hospital and Dispensary —House Physician and Surgeon Salary £120 per year with board, apartments and laundress

City of London Asylum —Second Assistant Medical Officer and Pathologist, unmarried Salary £150 a year, with board, apartments, and washing

Cumberland Infirmary Carlisle —Resident Medical Officer

Durham County Asylum —Assistant Medical Officer Salary £180 per annum rising to £220 with rooms and attendance.

East London Hospital for Children and Dispensary for Women Shadwell, E —Medical Officer for the Casualty Department for six months renewable Salary at rate of £100 per annum with luncheon. Also House Surgeon for six months with board and residence Honorarium of £25

Evelina Hospital for Sick Children Southwark S.E —Two Physicians to Out-patients

Hospital for Sick Children Great Ormond street London, W C —House Physician unmarried, for six months. Salary £20 with board and residence

London Throat Hospital, 204 Great Portland street W —House Surgeon (non resident) Honorarium at rate of £50 per annum.

London Temperance Hospital. Assistant Resident Medical Officer for six months Honorarium at rate of 50 guineas per annum with board and residence.

Manchester Owens College —Junior Demonstrator in Physiology Stipend £100 rising to £150 per annum

National Hospital for the Paralysed and Epileptic Queen square Bloomsbury —House Physician. Salary £100 with board and apartments

Newcastle on Tyne School Board —Two Medical Officers. One male one female

North Eastern Hospital for Children Hackney road Bethnal Green N E —Assistant Physician. Also Casualty Officer for six months Salary £80 with lunch

Queen Charlotte s Lying-in Hospital, Marylebone-road, N W —Assistant Resident Medical Officer for four months Salary at rate of £50 per annum with board residence and washing

Rotherham Hospital and Dispensary —Senior House Surgeon Salary £110 per annum, with rooms commons and washing

Royal Eye Hospital Southwark S.E —House Surgeon for six months renewable Salary 50 guineas per annum with board and residence

Staffordshire General Infirmary, Stafford —Assistant House Surgeon Salary £80 per annum, with board lodging, and washing

Stockport Infirmary —House Surgeon Salary at rate of £100 per annum with board, washing and residence

Victoria Children's Hospital, Park-street Hull.—Lady House Surgeon. Salary £50 per annum with board and laundry Also Lady Assistant House Surgeon Salary £40 per annum, with board and laundry

Warwick Union —Medical Officer Salary £140 per annum

West London Hospital Hammersmith road, W —Assistant Surgeon.

Walsall and District Hospital —House Surgeon unmarried Salary £100 per annum with apartments board and laundry

Frith —On Feb 15th at The Limes Rickmansworth the wife of Walter S Frith M.B B C Cantab of a son

Hicks —On Feb 12th at Huntingdon the wife of Charles H. Hicks M.R C S L R C P Lond of a son.

MARRIAGES

Charlesworth—Ram —On February 14th at Christchurch Cathedral Zanzibar Francis Charlesworth M B of H M s Agency Zanzibar, to Mary Frances Jane eldest daughter of the late Rev George Stopford Ram of Clonatin County Wexford vicar of St. Peter's Bournemouth and of the Hon Mrs. Ram of 59 Courtfield gardens S W

Richardson—McLean —On Feb 11th at St. Paul s Church Clifton, Bristol by the Rev A. H Sewell M.A. Hugh Richardson M B C M Edin (late R.A.M C) St Andrews son of the late Henry Cockburn Richardson I C S to Elizabeth daughter of the late Patrick McLean

DEATHS

Dixey —On Feb 13th at his residence Moss Hall Villa North Finchley Augustus Edward Dixey M D St. And

Halliburton —On Feb 16th at The Oaks Grange-road Upper Norwood S.E Thomas Halliburton in his 80th year

N.B —A fee of 5s is charged for the insertion of Notices of Births, Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL MAN THE CORONER AND THE PATHOLOGIST

DEPUTATIONS from the staff of St Thomas's Hospital and the practitioners in the south-western district of London were received by the public control committee of the London County Council on Feb 13th and made a representation of the situation that has arisen out of the innovations introduced by Mr Troutbeck into his coroner's court *The public control committee went carefully into* the representations made to it and will no doubt make a report which will be presented to the Council and become public property

The *Wandsworth Borough News* of Feb 13th contains lengthy accounts of two inquests conducted by Mr Troutbeck in the course of each of which the coroner pointed out to the jury the reasons for calling upon Dr L. Freyberger to make post-mortem examinations. As long as Mr Troutbeck, in defence of his own innovations misrepresents the medical profession so long we shall be compelled to re-state the true position of affairs. The first of the two inquests was upon an infant who died from rupture of a malformed heart. Mr Troutbeck, at the Battersea coroner's court suggested that if he had not had specially skilled assistance the jury might have been led into thinking that the child's death was due to suffocation. Dr Freyberger could have told him what as a lawyer he is not likely to know that no special knowledge whatever is necessary to detect such a condition post mortem and that there may have been excellent material for diagnosing the condition while the infant was alive. In addressing the jury in this case Mr Troutbeck is reported to have justified his action in not having subpœnaed the medical attendant on the ground of economy But we understand that Dr Freyberger has offered his services to the London County Council at the statutory fee of two guineas For the same sum Mr Troutbeck could have had the evidence dealing with the symptoms of the infant while alive and the conditions after death from the best person to describe them—viz. the medical practitioner in attendance upon the case while for half that sum he might have obtained from the medical practitioner sufficient evidence to result in a proper verdict. We do not see in what way Mr Troutbeck has saved any waste of public funds

The second inquest reported in the *Wandsworth Borough News* of the same date was held at the Wandsworth Town Hall and was also upon an infant The infant during life was attended by two medical men one of whom the one who had only seen the child in a dying condition was called by the coroner Evidence was also given as to the post-mortem conditions by Dr Freyberger in the medical practitioner's presence and he very properly told the coroner that as a matter of fact Dr Freyberger had not touched the body Dr Freyberger said that he suffered from sore hands and therefore employed the post-mortem porter paid by the borough council, to open the body He added that he had done the same in thousands of cases. It appeared that the attendant did not open the heart and that Dr Freyberger arrived at his conclusions regarding this organ from external appearances We see no harm in the porter occasionally doing the manual work, or portions of the manual work, of the investigation under Dr Freyberger's or preferably under the medical adviser's eye but think it unfortunate that Dr Freyberger should not be in a physical condition to touch a corpse An attendant can not take the place of a skilled pathologist: *tactus eruditus* is required to detect the friability of an organ or the density of an adhesion &c. and no coroner ought to look for such information from an attendant even though his wages are paid by the borough council. Why Dr Freyberger whose special knowledge of cardiac pathology was dwelt upon by the coroner in the previous case, made no examination of that essential organ the heart in this case we cannot pretend to guess. The medical practitioner who saw the child before death seems to have thought that there were grounds for believing a malformation to have been present and certainly the heart should have been opened. Nor do we understand why of the two medical men who could have given evidence as to the symptoms before death the one who had the shortest opportunity of so doing was subpœnaed to help the jury

YELLOW FEVER.

IN an address delivered at the opening of the Washington Post Graduate Medical School on Jan. 12th and published in the February number of the *Popular Science Monthly* Surgeon-General George M Sternberg enumerated many instances of the success of modern methods of dealing with epidemic diseases With regard to yellow fever he said that Havana had for many years been the principal focus of infection in the West Indies and the port from which it had been repeatedly carried to the seaport cities of the United States but a great change for the better had come about during the last few years. According to the reports of the health officers in that city there had not been a case of yellow fever in Havana for more than a year and the extinction of the disease was ascribed entirely to the vigorous measures enforced to prevent its transmission by mosquitoes of the species proved by the researches of Reed and Carroll to be the immediate hosts of the yellow fever parasite and the active agents in the transmission of the disease from man to man. During the first 60 years of the past century yellow fever prevailed almost annually in one or more of the southern seaports of the United States and not infrequently it extended its ravages to the interior towns in one or more of the southern states. So frequently did it prevail during the summer months in New Orleans and Charleston that the permanent residents of those cities commonly regarded it as a disease of the climate and as a necessary evil which it was folly to attempt to combat by quarantine restrictions In the great epidemic of 1853 yellow fever prevailed extensively in the states of Florida, Alabama, Louisiana, Mississippi Arkansas, and Texas The epidemic of 1867 was limited to the states of Louisiana and Texas. Those states again suffered severely in 1873 and the states of Florida, Alabama, and Mississippi were also invaded. A still more extended and deadly epidemic occurred in 1878 causing a mortality of 15 934 out of a total number of cases exceeding 74 000 In this epidemic the disease followed the Mississippi river to the very suburbs of St. Louis, the state of Tennessee suffered severely as well as the states south of it and the city of Memphis alone had a mortality from the disease of about 5000

MULTIPLE GONOCOCCUS INFECTION

DR. JOSEPH L BOEHM of St. Louis Missouri has published in the January number of the *St. Louis Courier of Medicine* a case of multiple gonococcus infection occurring in a boy 16 years of age who was admitted into hospital with granular inflammation of the conjunctiva. He had been suffering from a purulent discharge from the urethra for about four weeks but had otherwise been in good health Pus from his eye was found to contain the gonococcus His temperature was 103° F On the second day his pulse-rate was 140 there was a distinct systolic murmur at the cardiac apex and the diagnosis of endocarditis was made. His temperature at night was 100° Three days afterwards his left ankle-joint was painful œdematous and hot. Next morning the left knee was painful and fully three inches larger in circumference than the right knee. On the next day the two shoulder-joints were affected. He afterwards became delirious and so ill that a fatal issue was expected but eventually he recovered. He was given a mixture containing guaiacol carbonate, sodium salicylate, and benzoic acid Ice-packs were applied to the head and over the heart and the joints were strapped, fluid being also aspirated from the knee-joint

UNFORTUNATE ADVERTISEMENT

THE following paragraph is taken from the *General Advertiser* a Dublin newspaper and we are requested to give an opinion upon it

> INDIGESTION
>
> LOSS OF APPETITE, FLATULENCY, BILIOUSNESS
>
> SIR C CAMERON M.D reports— I can strongly recommend EARL'S FLUID PEPSINE as a reliable Remedy for Indigestion and Dyspepsia. It contains the digestive properties of the gastric juice in a highly concentrated permanent and reliable form. It causes even the toughest beef to become digested is peculiarly suitable for invalids and young children and is superior both in strength and efficacy to any other preparation of Pepsine" Of all Chemists and Druggists in bottles, 1s. 3s 5s. 6d. 10s. 6d.—Central Depôt, 12, Grafton Street

Our view is that Sir Charles Cameron should instruct the proprietors of Earl's Fluid Pepsine to discontinue the use of his name in connexion with their wares in the lay press.

WEST INDIAN COLONIAL MEDICAL SERVICE.

M.R C S L.R.C.P is anxious to correspond with any medical man who has served in the West Indian Medical Service and who could inform him fully on the subject

THE CHEAP PISTOL AGAIN

A TYPICAL accident with a toy pistol formed the subject of investigation at an inquest held recently at Bromley A lad, aged 17 years a milk carrier bought from one of his companions a pistol and a few cartridges for a shilling He appears to have tested its capacity for destruction by firing it at a fence when the bullet went through a rail and into a field A few days later he produced it from his pocket showed it to two companions and loaded it. His companions had left him and apparently he was replacing it in his trousers pocket when it went off wounding him in the lower part of the abdomen. He was taken to the cottage hospital and treated without delay but peritonitis supervened and two days after receiving the wound he died A curious feature in the case was that he stated to Dr H. J Ilott, when he first examined him, that another boy shot him at a distance of five or six yards. This statement would have thrown grave and unjust suspicion upon the boys who were both within 20 yards when the accident took place had not the condition of the wounded lad's clothes and apron clearly pointed to the pistol having gone off in his pocket. He also before dying retracted his former statement and said that the pistol went off in his own hand by accident Dr Ilott informed the jury that in two years he had treated four wounds from such pistols as that which the deceased had owned a weapon which is no doubt still in the hands of somebody at Bromley for one of the lads said that he threw it away after the accident and it has not been found since. The jury expressed an opinion that some restriction ought to be placed on the sale of toy pistols and cartridges but it seems useless to hope for this Something will no doubt be done when some conspicuous personage has been shot until then this peculiarly useless and dangerous commerce will presumably continue unchecked

NON LEAKABLE FOUNTAIN PEN

To the Editors of The Lancet

Sirs —You refer in The Lancet of Feb 14th p 450 to a non leakable fountain pen in which the principle of the closure of the reservoir by pushing the pen up into writing position and the arrangement by which ' the cap can be replaced over the nib in such a way as both to protect the nib and to close the ink reservoir is referred to as ' something quite new " This description tallies with that of the Caw fountain pen which I and others have used for many years It has given perfect satisfaction as a non leakable fountain pen, differing in this respect from all other pens with which I am acquainted I am Sirs yours faithfully

' THE PRESCRIBING QUACK.

In The Lancet of Feb 7th p 411 we animadverted very strongly upon the conduct of Mr F E Bustard M.P S in sending out an advertisement of a disgraceful nature We are glad to see that our contemporary the *Pharmaceutical Journal* in a paragraph on page 217 of the issue of Feb 14th agrees with our remarks the paragraph being headed as above Our contemporary further says that as further action may be taken in the matter it is not desirable to comment upon the circumstances at present but the hope may be expressed that no other registered chemist is endeavouring to extend his business by unprofessional means similar to those to which The Lancet has very properly taken exception " It is fair to say further that our contemporary states that Mr Bustard has confirmed the accuracy of our note but that the card was withdrawn from circulation about three weeks ago We have moreover received the following letter and we congratulate the Pharmaceutical Society upon its prompt action.

Pharmaceutical Society of Great Britain
17 Bloomsbury-square London, W C

To the Editors of The Lancet

Sirs,—I have observed the note in your issue of the 7th inst headed The Prescribing Quack and have to inform you that the person therein referred to is no longer a member of this society and will not be permitted to continue to use the initials M P S I am Sirs *yours faithfully*

Feb 16th 1903 R Bremridge Secretary and Registrar

A FORMALDEHYDE INHALER

Dr Chowry Muthu has designed a simple appliance for formaldehyde inhalation which he regards as a very important aid in the treatment of pulmonary tuberculosis The inhaler consists of perforated zinc and is pyramidal in shape the base resting on the chin and the apex on the nose It is flexible so that it can be readily fitted. The following mixture is sprinkled on a pad of cotton wool: one drachm of formalin one drachm of chloroform and two drachms of rectified spirit The inhaler is light and portable and can be used at all times of the day whether the patient is reading writing or walking Dr Chowry Muthu points out that the success of this apparatus depends on its being used constantly and perseveringly for six or seven hours a day and even at night The inhaler is supplied by Messrs Maw, Son and Sons 7 Aldersgate-street London E C

MOTOR CARS FOR MEDICAL MEN

To the Editors of The Lancet

Sirs —Perhaps some of your readers may like to hear particulars of a good second hand steam car and also a 10-h p Panhard suitable for medical men They were built less than a year ago for a wealthy private motorist and are now privately offered for sale at a low price. Each car has been little used and can be inspected and fully tried before purchase I am, Sirs yours faithfully

An Address

ON

SOME FAMOUS MEDICAL OFFICERS OF THE ARMY.

Delivered to the Royal Army Medical Corps Staff College at the Examination Hall, Victoria Embankment, on Feb 18th, 1903

By NORMAN MOORE, M.D CANTAB,
F R C P LOND,
PHYSICIAN TO AND LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE AT ST BARTHOLOMEW'S HOSPITAL.

GENTLEMEN —The medical officers of an army appear in one of the earliest and most celebrated pieces of literature[1]—

ἰητροὶ μὲν γὰρ Ποδαλείριος ἠδὲ Μαχάων—

and Homer represents them as held in due honour at the siege of Troy[2] —

ἰητρὸς γὰρ ἀνὴρ πολλῶν ἀντάξιος ἄλλων
ἰούς τ' ἐκτάμνειν ἐπί τ' ἤπια φάρμακα πάσσειν

("For a medical officer is worth many men
To cut out arrows and spread soothing remedies")

and such was their fame that Podaleirios, according to Strabo, was afterwards worshipped on Mount Dria.

The story in Arrian's *Ἀνάβασις Ἀλεξάνδρου* is worth remembering as a proof of the high esteem in which the greatest general of the Greek world held his principal medical officer "Alexander" says Arrian, "was seized with pains in the nerves, accompanied with a sharp fever and a continual waking, insomuch that when all the rest of his physicians despaired of his life Philip the Acarnanian, in whose extraordinary skill in physic he had great confidence because of his success in the camp, was ordered to administer a draught to him. After these orders were given, while he was preparing the cup, came a letter from Parmenio to Alexander warning him to beware of Philip, for that he had heard how Philip had been bribed by Darius to poison him. Alexander having read the letter took the cup wherein was the potion, in his hand and gave Philip the letter to read, and while he was reading he drank up the draught, the physician showing by the composure of his countenance that the medicine was inoffensive and by his intrepidity on perusing the letter that he was not conscious of any crime that he had been guilty of He only entreated Alexander to acquiesce in his advice in what he should prescribe for the future, which if he did he would recover his health After his disease had left him he declared his esteem for Philip by assuring him that he should always have a share in his friendship and certified to all who were present how steady an opinion he retained of their loyalty in refusing to entertain any suspicions to the contrary, as also that he could meet death with a true heroic magnanimity "[3]

You will remember that Flavius Arrianus, who was as good a general as he was a man of letters, was the pupil of Epictetus and lived in the second century of our era but that his lucid *Ἀνάβασις Ἀλεξάνδρου* is based on the contemporary records of Alexander If our army should ever be engaged in military operations in the region of Alexander's campaigns it would be interesting if some member of your corps were in any spare moments to consider on the spot the passages of Arrian and of Plutarch which relate to the death of Alexander The history of his illness is simple, as stated in the concise ephemerides kept by his secretaries He was slightly unwell yet supped two nights at the house of Medius after the obsequies of his friend Hephœstion The day after which was June 18th he was distinctly feverish but ate a full meal. He had a daily access of fever in the evening till the 25th, when his fever having greatly increased he became unconscious and died on the evening of June 28th, the twelfth day after he was distinctly ill. Though he kept his bed from the 19th he tried till the 25th to transact business and was carried out to assist at sacrifices and seems to have been out of bed for this purpose. He had disturbed nights and his fever increased from day to day He was 32 years and eight months old at the time of his death.

Arrian is careful to distinguish between facts stated by later or less authentic writers and those contained in the ephemerides or royal diary He says "The royal diary gives us an account that he ate and drank with Medius and then retired to rest and when he awaked and had washed and refreshed himself he again supped with Medius and drank till late at night. When he retired from the banquet and had washed he ate a little and lay down because he had some symptoms of a fever Afterwards he was carried in a chair to the temple and there sacrificed after his usual manner and this he repeated several days and when the sacrifices were performed he lay in an apartment prepared on purpose for him till the evening In the meanwhile he issued out orders to the captains of his troops to make ready for a march in four days' time and even nominated those who should travel on foot, but those who were to go on board the fleet with him were to prepare themselves against the fifth day • After this he was carried to the river and being put on board one of his gallies was conveyed to some pleasant gardens on the other side where after he had washed he went to rest. The next day he again bathed and performed his accustomed sacrifices and held discourse with Medius, having given orders to his officers to attend him in the morning He then supped moderately and being conveyed to bed had a continued fever upon him all that night. However, the next morning he again washed and sacrificed and ordered Nearchus and the rest of his captains to prepare for sailing the third day The next day he washed and sacrificed as before, but this fever still continued, notwithstanding which he again called his captains to him and ordered all things to be made ready for a voyage, and, having bathed, his fever increased towards evening The next day he was carried into a house adjacent to the bath, where he performed his usual sacrifices and once more called his chief officers about him to give orders concerning the intended voyage The day following he was with great difficulty carried to sacrifice and, notwithstanding he grew manifestly worse, could not be restrained from sacrificing the day after that. He then commanded his chief officers to remain with him in the hall and the inferior ones to wait at the gates, and growing still worse, he was conveyed from the hall in the garden where he then was into the palace, and his chief officers approaching near he made signs that he knew them but was not able to speak and thus he remained all that night The day following the fever still increased and all that night and the next day continued strong and violent And now his soldiers expressed a great desire to see their king some doubting whether he was alive, others plainly affirming that he was dead but that his death was concealed by his bodyguards, and to such a height at last did their grief drive them that many of them forced their way through the guards and entered the royal apartment. But though the king perceived them his speech had left him, however with much difficulty he lifted up his head and looking upon them stretched forth his hand to each of them. The same royal diary also informs us that Python Attalus, Demophoon, Peucestas, Cleomenes, Menidas and Seleucus tarried all night in the temple of Serapis and having asked that god whether it would not be better for Alexander to be brought into his temple to be restored to health by him were answered by the oracle that he should not be brought, for it was best for him to continue where he was This answer was brought back to Alexander by his friends and in a short while after, as if the oracle had pronounced that best he died. Ptolemy and Aristobulus in their accounts of these transactions differ not much from the royal diary "

M. Littré in a very interesting essay[4] published in 1853 points out that some later tales of poisoning as a cause of the death of Alexander are not supported by the evidence which points distinctly to a natural disease and concludes that the fever was a malarial one. The history of death on the twelfth day of well marked illness with some indication of preceding diminution of health for a further period, the evening rise of temperature going on to higher and uninterrupted fever, added to the fact that the patient did not take absolute rest in bed and did not take to bed at the beginning till absolutely compelled to do so by the blade broken off near the hilt, with many wounds on his head. I, seeing the hairy scalp of one side of his head hanging down his neck, went to him, and calling my friend Will Clarke to me with a sponge to cleanse the wound we saw six pieces of the skull sticking to it some of them were of the first table others of both tables Besides which there were various fissures, sedes, and some fractures with depression, made by sword, musket-stock, and &c We freed the scalp of those bones and returned it upward so far as we judged was necessary , then cutting off what was superfluous, tacked it to the sound parts by several stitches distant from one another, leaving a space to dress the depression and greater fractures Then we dressed up the wounds with digestives ex terebinth and &c., and where the dura mater lay bare we applied pledgits dipped in ol. ros., and to the other parts of the cranium liniment arcei. The alarm growing hot of the enemies entering the city, I left Will Clarke to bind it up and made my way out of the town But this young chirurgeon being taken busied in dressing the wounded soldiers had liberty, after the heat of the fight was over, to employ his charity in dressing some of them and write me since this soldier's particular case—viz , the third day he found him pretty hearty and his wounds mattering so very much that he was necessitated to cut loose two of the stitches to give vent to it then he dressed the penetrating wounds with mel. ros and the cranium with lint pressed out of spir vini and proceeding accordingly in the cure saw the depressed and mangled bones cast off, incarn, and cicatrize with the rest. The soldier being thus cured by him made a voyage to the Indies and since that served a soldier in the Tower of London " An excellent life of this surgeon was published in 1891 by a member of your own corps, Surgeon General Sir T Longmore.

[2] Iliad xi 514.

[3] Rooke's Arrian London 1729 Book i., cap. iv

[4] De la Toxicologie dans l'Histoire et de la Mort d'Alexandre.

The battle of Worcester put an end for the time to the king's cause in the British Isles, so that the loyalty of Dr William Petty, who in 1652 was appointed physician to the army in Ireland, cannot be called in question, especially as on the restoration the king received him and knighted him on April 11th 1661.' Sir William Petty was so distinguished a man that I should be sorry to omit him from your record, the more so as his descendant, the present Lord Lansdowne, is a statesman whose influence has been directly felt by the Royal Army Medical Corps. Petty will always be remembered as the author of the first English treatises on political economy, "Political Arithmetic," and "Several Essays in Political Arithmetic " In one of these essays he endeavours to prove that London has more people than Paris and that they are better provided for, and he uses the then state of the London hospitals as an illustration "In the hospital of St Bartholomew in London there was sent out and cured in the year 1685, 1764 persons and there died out of the said hospital two hundred fifty and two Moreover, there were sent and cured out of St Thomas's Hospital one thousand five hundred twenty and three, and buried two hundred and nine, that is to say, there were cured in both hospitals three thousand two hundred eighty and seven, and buried out of both hospitals four hundred sixty and one, and consequently cured and buried three thousand seven hundred and forty and eight, of which number the four hundred sixty and one buried is less than an eighth part, whereas at La Charité the part that died was more than an eighth part which shows that out of the most poor and wretched hospitals of London there died fewer in proportion than out of the best in Paris."[11]

The most ancient office in your department of surgical practice is the king's serjeant-surgeoncy It is a duty of the king's serjeant-surgeon to attend the sovereign on the field of battle. The distinguished surgeon who at present holds this office has shown his readiness to take part in the labour and hardships of a campaign and has also as we all know, by the skilful practice of his art preserved the King's life in a situation not less dangerous than many hazards of the field, but Sir Frederick Treves has not had the chance of discharging the original military service of a serjeant surgeon since the exigencies of affairs have not called our sovereign into battle for a long time. John Ranby, who was appointed serjeant-surgeon to King George II , was present with that king at the battle of Dettingen in 1743. His Majesty dismounting from a restive horse fought on foot and his son, the Duke of Cumberland, was severely wounded In a little treatise on gunshot wounds Ranby describes the duke's case[12] A grape-shot from a cannon went through the calf of his leg and the orifices of entrance and of exit of the shot were each as big as a hen's egg The wound did well and there was no subsequent stiffness

It would be easy to draw from the annals of your corps many more interesting histories or valuable observations of disease or of wounds and we might spend a long time in the consideration of its representatives throughout the years of the war in the Peninsula, on the field of Waterloo, and in relation to the marches, the battles, the sieges, and the epidemics of India, in every climate and under every condition of success and of disaster, but I have only time to mention two more of its famous men, one a regimental surgeon and the other a physician to the army

George Cleghorn, a native of Scotland and a graduate of Edinburgh, was appointed surgeon to the 22nd Regiment of Foot in 1736 The regiment was stationed in Minorca and remained there till 1749 Cleghorn occupied his spare time in writing "Observations on the Epidemical Diseases in Minorca from the year 1744 to 1749 " Four editions of this excellent book appeared in the author's lifetime. It is full of original observations and deserves a permanent place in English medical libraries. He gives a thorough account of the physical geography, climate, agriculture, botany, and zoology of the island. He describes the natives and their habits of life and observes what customs described in Theocritus, Virgil, and Lucretius were still maintained in Minorca. He goes on to relate the diseases which he had observed and gives an account of diseases which were clearly enteric fever complicated with tertian ague, with pneumonia, and with dysentery and keeps strictly to what he had observed at the bedside. He took the temperature with a thermometer, a rare proceeding in his period, and notes that in cases of epidemic pleuro pneumonia it was raised to 102° or even 104° F 21 patients died from this epidemic and he examined 14 post mortem and gives a full account of the morbid appearances. Cleghorn's complete and accurate account of the natural history, physical conditions, and pathology of Minorca is valuable in itself and is further of use as an example of a kind of work which a medical officer of the army may do for any particular station with great advantage to medical knowledge in general. After he left the army he settled in Dublin where he became professor of anatomy in the university He died in 1789

Richard Brocklesby, who in 1758 was appointed physician to the army, was born in 1723 at Minehead in Somersetshire but was sent to school in Ireland. The school to which he was sent was kept at Ballitore, co Kildare, by Abraham Shackleton and Brocklesby had been there seven years when a boy entered who was destined to make the school and its master for ever remembered , this was Edmund Burke. The friendship which grew up between him and Brocklesby lasted for life and when Brocklesby settled in practice in London he enjoyed the friendship of both Burke and Johnson and lived in the most illustrious circle known in the history of our literature He was both generous and learned In July 1788, he wrote to Burke giving him £1000 and said he would be happy to repeat the gift "every year till your merit be rewarded as it ought to be at court." He was generous in the same way to Johnson, and Boswell tells "as an instance of extraordinary liberality of friendship he told us that Dr Brocklesby had on that occasion offered him a hundred a year for his life. A grateful tear started into his eye as he spoke this in a faltering tone." He gave to the College of Physicians a splendid copy of the 25 volumes of the great collection on classical antiquities known as the "Thesaurus" of Grævius and Gronovius, and generosity with him was a constant habit and not an occasional impulse. He wrote an interesting little book on the regular use of music in medicine It probably became the subject of his thoughts through a story he heard in Edinburgh of a Jacobite gentleman who lost two sons and was himself wounded in the rising of 1715 and who fell into a melancholy accompanied by fever till his physician cheered him by making a Highland harper play to him every day His most valuable book was published in 1764 "Œconomical and Medical Observations in Two Parts " This book laid down for the first time sound principles of hygiene for the army

There were then few barracks and most of them were very ill arranged buildings. Brocklesby shows that the soldiers must have plenty of air in their rooms if they are to remain healthy He draws up proper regulations for field hospitals and thinks that the doctor ought to be supreme in the hospital, which was not then the case His observations on diseases of camps are lucid and original and all he says on treatment is full of good sense. There was a tendency at that time to appoint men with but little knowledge of medicine and Brocklesby dwells on the importance to the army of that part of our profession with which physicians are principally concerned [13] "That the business of every regimental practitioner is at all times much more the subject of medical consideration and of cool reflection, than of mechanical dexterity in dressing, or even in cutting off a limb will appear to the meanest capacity, who stands informed of the following fact, well vouched to me by a very ingenious and worthy man, who was seven years surgeon to a regiment in the late war, during which, the corps had been two campaigns upon very hard service, and had also sustained the severest shocks and losses which attended the tedious siege of the Havana. Yet the surgeon declares, that in full seven years, he had never met with near 100 properly chirurgical cases in the whole regiment, though in that course of time near 2000 men had gone through the regimental books, including about 400 draughted out of it into different corps May we not then justly conclude, that in time of profound peace, the exigencies of chirurgical dexterity compared to the objects of medical attention, in any regiment, are at most, one half less than they had been observed in two battles and one siege, besides, the rest of the seven years consequently that the medical science requisite for a regiment, is at least forty times necessary to be in some sort practised for once that any particular dexterity in manual operations, or surgery is required."

[11] Sir William Petty: Several Essays in Political Arithmetic. London 1699 p. 94

[12] John Ranby: The Method of Treating Gunshot Wounds London 1781, p 45.

There is no need at the present day to insist on this contention of Brocklesby The more enlightened conditions of medical education give to every practitioner sufficient knowledge of medicine and of pathology to interest him for life in all diseases and their treatment as well as in injuries and operations When you remember that in an ordinary epidemic of enteric fever there is a percentage of deaths five times as great as that of the killed in the battle of Waterloo and that enteric fever is a common incident of a campaign, or if you open the medical report of the civil war in the United States and learn that on the side of the North alone 50 000 men died from dysentery, you need no further arguments to prove that the highest attainments in medicine will find abundant employment in the army whether in war or in peace

Brocklesby's mind was stored with learning and his conversation was such as was worthy of an associate of Burke and of Johnson. Johnson objected to the practice of making puns in which Burke now and then indulged One of them was on Brocklesby's name, and I mention it as a pleasant example of the *familiar relation* existing between the physician and his illustrious schoolfellow There was in their time a quack doctor in London called Dr. Rock Burke by accident or out of mischief one day called Brocklesby Dr Rock, and when Brocklesby remonstrated Burke said that he would prove algebraically that Rock was Brocklesby's true name Brock minus B equals Rock, and what is that but Brock less b' Brocklesby was physician to Dr Johnson and attended him in his last illness Two incidents of this attendance are related by Boswell.

"About eight or ten days before his death, when Dr Brocklesby paid him his morning visit he seemed very low and desponding and said I have been as a dying man all night. He then emphatically broke out in the words of Shakespeare —

> Canst thou not minister to a mind diseased
> Pluck from the memory a rooted sorrow
> Raze out the written troubles of the brain
> And, with some sweet oblivious antidote
> Cleanse the stuff'd bosom of that perilous stuff
> Which weighs upon the heart?

To which Dr Brocklesby readily answered from the same great poet —

> Therein the patient
> Must minister to himself

Johnson expressed himself much satisfied with the application.

On another day after this, when talking on the subject of prayer, Dr. Brocklesby repeated from Juvenal —

> Orandum est, ut sit mens sana in corpore sano

and so on to the end of the tenth satire, but in running quickly over he happened in the line,

> Qui spatium vitæ extremum inter munera ponat

it to pronounce 'supremum' for 'extremum,' at which Johnson's critical ear instantly took offence and discoursing vehemently on the unmetrical effect of such a relapse he showed himself as full as ever of the spirit of the grammarian

Brocklesby died on Dec. 11th, 1797 and left his house, pictures, books, and a considerable fortune to his great nephew, Thomas Young, to whom he had always shown much kindness and who deserved it, for while a student of about 20 years at St. Bartholomew's Hospital he wrote so original a memoir on sight that he was elected a Fellow of the Royal Society and in after life he became famous as the originator of the undulatory theory of light and the earliest interpreter of the Egyptian hieroglyphics. Thus was Brocklesby useful and happy in his life and fortunate in his friendships To have been the benefactor of three such men as Burke, Johnson, and Young to have shared their conversation and to have enjoyed their esteem is perhaps the highest distinction which has ever been attained by any member of the Army Medical Service

Such were a few of the many celebrated men of your branch of our profession. It would be easy to tell of many more whose lives or whose writings deserve attention and remembrance, and it is an interesting circumstance that the first lectureship in the history of medicine in the United Kingdom has recently been founded to commemorate a very learned and worthy man who began his professional life in the Indian branch of the military medical service, Dr. Thomas Fitz Patrick.

The study of the past in medicine is more than a mere archæological pursuit, it ought to be so used as to be of present service to its student. The observations of every man who has stated to the best of his ability what he saw are of permanent value, of the same kind of use, in fact, as the reports of living cases. A part of the method of diagnosis is the weighing of the circumstances of a history, and where these are clearly stated the exercise is useful though the patient is not himself before us This is what may be called the practical value of a study of the medical writings of past times. They are instructive, too, as warning us how easy it is to be misled as to what we are looking at, or touching by some preconceived hypothesis. This is a lesson which cannot be too often inculcated, everyone engaged in practice knows how often the impression conveyed to him beforehand may mislead him in diagnosis by inducing him to attach too much weight to one fact or too little weight to some other, though both have been observed by himself. The habit of precise consideration of every observation and of rigid logical deduction from our observations can only be acquired in medicine and when acquired can only be retained by constant exercise in every possible direction, and it is as a part of this training that the perusal and consideration of the cases of past times are important to everyone engaged in the practice of medicine and surgery Besides this use the knowledge of the work done the difficulties surmounted and the discoveries made by our predecessors in science and in practice elevates the tone of our professional life, and urges us to be worthy associates in history of those who have added to knowledge and been constant in duty

SOUTHEND-ON-SEA AND DISTRICT MEDICAL SOCIETY —The second annual meeting of this society, postponed from October, was held on Feb. 10th. The following officers were elected President Dr A. Clough Waters, J P, vice-president Mr G F Jones, committee, Mr C H. Wade, Mr H. Cleveland Smith and Dr A. Grosvenor Hinks, honorary secretary, Mr J B. Maxwell. The following gentlemen were elected honorary members Dr T Outterson Wood and Mr C W Mansell Moullin.—An address was then given by Mr Mansell Moullin on Gastric Ulcer from a Surgical Point of View and Hints when to Operate in Appendicitis.—A discussion followed, in which the following gentlemen took part the President, Dr J T C Nash Dr C Forsyth, and Dr A G Hinks —The members afterwards dined together at the Queen's Hotel, the President being in the chair About 30 members and guests were present.

An Address

ON

GASTRO-ENTEROSTOMY AND ITS USES, WITH A DESCRIPTION OF THE OPERATION AS PERFORMED BY THE AUTHOR.

Delivered before the Oxford Medical Society on Nov 14th, 1902,

By A W MAYO ROBSON, F R.C S Eng,
VICE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

Mr President and Gentlemen,—It is only 21 years ago since Nicoladini first suggested the possibility of making an anastomosis between the stomach and small intestine so as to short-circuit obstruction at the pylorus At that time, and for some years later, so little confidence was placed in this and similar operations on the stomach that patients, as a rule, were treated medically until almost moribund before being handed over to the surgeon, with the result that the mortality was appalling This naturally retarded progress, since the deaths following on operations in moribund cases were mistaken for deaths due to the operation itself, and when we take into account the fact that out of 35 cases in which gastro-enterostomy was performed between the years 1881 and 1885 there were only 12 recoveries—in other words, that the mortality was 65 71 per cent —it is not to be wondered at that little confidence was placed in surgical methods It rather reminds one of the beginnings of ovariotomy, in which the mortality was still higher, and it accounts for the prejudice against recommending surgical treatment that existed for many years among physicians and that still exists among many of the older practitioners and in some of the more conservative schools. Even when I gave the Hunterian lectures on the Surgery of the Stomach at the Royal College of Surgeons of England in 1899, out of 1978 cases of gastro enterostomy that I was able to collect from all sources there had been a mortality of 36 4 per cent.—not a very encouraging outlook when one patient out of every 2 75 might be expected to die It is, however, a very different tale that I am able to tell to day, only three years later when I can point to a considerable series of cases with a mortality of under 5 per cent This—I venture to think will be granted—brings the operation within the realm of comparative safety, and seeing that it has to be undertaken in many cases for diseases that would be otherwise inevitably fatal, it may be looked on as an operation the benefits of which not even the most conservative among us can afford to ignore.

These changes have been brought about, not only by patients being operated on at an earlier stage and under more favourable conditions—for many of my patients have been extremely ill at the time of operation—but also by greater care in technical details, by greater expedition in operating, by more careful asepsis, by the avoidance of, or greater care in the use of, irritating antiseptics, by the prevention or better treatment of shock, by care in post-operative treatment such as early feeding subsequently to the operation, and by the careful preparation of the patient before the operation

I will endeavour in the time placed at my disposal this evening to point out in detail the methods which I employ and to illustrate my remarks by a description of a few of the cases on which I have operated

The preparation of the patient —It has been the custom with many surgeons to put patients suffering from disease of the stomach through a long course of preliminary treatment, such as frequent lavage of the stomach and abstention from food before operation This, as a rule, is quite un necessary and certainly inadvisable in the greater number of cases—first, because the treatment is depressing and debilitating in the case of patients already exhausted by a long illness, secondly, as proved by Dr Harvey Cushing's bacteriological investigations, the stomach contents speedily become aseptic if the mouth be cleansed and aseptic foods administered, and, thirdly as proved by ample clinical experience, elaborate preliminary treatment is unnecessary to success. If the stomach is greatly dilated and the contents are foul then lavage with simple boiled water night and morning is adopted for two days before operation. The careful cleansing of the mouth and teeth and the administration of foods sterilised by boiling are advisable. The last light meal is given the night before about 12 hours, the stomach is washed out about two hours, and a nutrient enema is given about one hour, before operation. In other cases no lavage is adopted, but the same care is exercised in cleansing the mouth, giving sterilised food, and administering a nutrient enema consisting of one ounce of brandy, one ounce of liquid peptonoids, and ten ounces of normal saline solution Every patient is enveloped in a suit of cotton wool made by the nurse out of gamgee tissue and each has an injection of liquor strychninæ (B P) administered subcutaneously before the operation is begun. The preparation of the skin and other aseptic details of the operation differ in no respect from those observed in operations generally

Although the operation of gastro-enterostomy has been performed in many different ways there are practically only two distinct methods—one Wolfler's, in which the jejunum is fixed to the anterior stomach wall, and the other von Hacker's, in which the anastomosis is effected between the jejunum and the posterior wall of the stomach From a somewhat extensive experience of the two I have no hesitation in strongly recommending the posterior where that operation is possible, for it must be granted that there are some exceptional cases where on account of adhesions to the pancreas, involvement of the posterior wall of the stomach by growth, or from congenital deformity the anterior method must be selected

In August I did two consecutive gastro-enterostomies in middle aged men in which the posterior operation was impracticable. In one, extensive ulceration had fixed the stomach to the structures lying behind it so that there was no free posterior stomach wall, in another extensive cancerous infiltration and adhesions prevented the stomach from being lifted up In October I also had to perform the anterior operation because of a congenital deformity in the shape of a very short transverse mesocolon.

My preference for the posterior operation, whilst at first based on theoretical considerations, has been supported by ample practical experience of its advantages, and the smooth recovery with absence of pain and vomiting that one is accustomed to witness leads me strongly to advocate the method. It affords free drainage of the stomach into the bowel and secures exact apposition by posture of the newly joined structures, hence there is little or no discomfort subsequently to operation and feeding may be begun quite early Moreover, as there is no loop of bowel constricting the colon there is no fear of obstruction, and owing to the unimpeded passage of the bowel contents, that distressing complication, regurgitant vomiting of bile, is, as a rule, avoided. In the practice of some surgeons this complication has followed so frequently that they have considerably modified Wolfler's operation in order to avoid it. In one of these modified operations an anastomosis is made between the afferent and efferent loops of jejunum, in another the loop of bowel is divided, the distal end being fixed to the stomach opening and the proximal end being inserted into the distal several inches away from the stomach These methods are certainly effectual, but as a routine practice they are unnecessary, and as they prolong the operation they must necessarily add to the risk.

The following is a description of the operation which I am in the habit of performing The abdomen is opened by an incision about four inches long, one inch to the right of the middle line, above the umbilicus. The stomach is thus exposed The jejunum is readily found by turning the omentum and transverse colon upwards, and feeling for its commencement on the left side of the second lumbar vertebra. A point about 13 inches from the commencement is chosen for the anastomosis in the anterior and one from six to nine inches for the posterior operation A loop is drawn out, milked until empty, and clamped with special forceps with long rubber-covered blades care being taken that the proximal end of the loop is towards the cardiac end of the stomach. The union of the viscera can be effected outside the abdomen, a long piece of gauze being packed round to isolate the operation area. In the anterior operation the point selected on the stomach for the union is near the pylorus and as close to the greater curvature as possible After the suture of the two orifices is complete a few additional stitches are introduced into the proximal end of the loop, securing it at a higher level on the stomach wall and also into the distal end, securing it at a lower level in order to obviate kinking In the posterior operation the transverse colon and great omentum are pulled upwards, exposing the under surface of the transverse mesocolon. A small slit is made in this and enlarged with the fingers, care being taken to avoid the wounding of any vessel. This, in case of adhesions on the posterior wall of the stomach, is sometimes simplified by passing the finger into the lesser peritoneal cavity through a thin place in the great omentum just below the stomach, the finger so introduced being used to press forward the transverse mesocolon where it is free from adhesions The posterior wall of the stomach is thus exposed and the portion which is to be sutured is drawn through the slit in the transverse mesocolon and clamped by the long slightly curved blades of a special pair of forceps covered with rubber so as to avoid crushing the stomach wall. The lateral margins of the incision in the transverse mesocolon may be stitched on each side to the stomach by a single suture in order to prevent closure of the slit and consequent narrowing of the jejunum as noticed by Czerny, though this is not necessary when the bobbin is employed. The union of the viscera may be effected in both anterior and posterior operations in one of three ways—(1) by simple suture, (2) by my decalcified bone bobbin, and (3) by a Murphy button The suture employed in (1) and (2) is practically the same The bobbin is used as a splint upon which the stitches are applied. By its use an immediately patent opening of a known size is secured and the bobbin is digested within 48 hours after it has effected its purpose Murphy's button is generally used only when the greatest haste is desirable. As the stitching in either of the two former methods can be done in from four to eight minutes by practised hands the button is rarely, if ever necessary Mikulicz regularly employs it and speaks well of it, and many other surgeons prefer its use to all other methods. If, however, its one advantage, rapidity is negatived by the operator having accustomed himself to the details of simple suture the button can only be harmful and it is a well recognised fact that it very frequently falls back into the stomach and is there retained. Now, although it may do no harm in some cases yet it cannot be desirable, especially in an ulcerated stomach, to have a hard foreign body permanently retained in its cavity

Method of stitching—The stomach and intestine being placed in apposition, a continuous Lembert stitch of spun celluloid thread unites the serous surface for a distance of two inches or more. The line of this stitch is semi oval and joins the surfaces of the viscera close to the posterior border of the anastomotic opening Incisions are then made into the viscera in front of the suture. A second continuous suture is now passed uniting the posterior cut edges, this may take only the mucous membrane or all the coats and is of catgut. After completing the posterior half the bobbin is introduced. The anterior semi-circles of stitches are now continued first the catgut circle to the cut edges and then the celluloid circle to the serous coats, in precisely the same fashion as the posterior sutures were applied. If the bobbin is used the sutures are drawn firmly on to it in tying If not, the stitch must be interrupted at one point or more in order to prevent the suture "drawing' and puckering the orifice.

Removal of mucous membrane—Chlumskij in reporting from the clinic of Mikulicz the results of gastro-enterostomy in which the simple suture had been used found that in all, the opening was not of adequate size. This lessening in the size of the opening may be due either to cicatricial contraction or to thickening and pouting of the mucous membrane at the orifice. Kelling[1] states that the chief advantage of the Murphy button over simple suture is the prevention of the formation of a ring of mucous membrane which projects into the stomach and occludes the new opening To avoid this it will be found helpful to remove a small portion of the mucous membrane of each viscus This may be done in the following manner When incising the gut the serous and subserous layer are cut through carefully The mucous membrane then bulges into the wound, is seized with nibbed forceps, loosened on each side from the submucous coat, and an ellipse of it as long as the wound and three-quarters of an inch broad is cut away This procedure has given satisfactory results but it is not necessary when using the bobbin The clamps and gauze are now removed and the viscera are carefully replaced in position, after which the abdomen is closed by a continuous catgut suture which first unites the peritoneum and posterior rectus sheath together and the same suture returning unites the anterior sheath of the rectus The skin is brought together with a continuous catgut suture or with several interrupted silkworm gut or green chromic catgut sutures

Special complications that may follow the operation of gastro-enterostomy—1 Regurgitant vomiting has been very much more frequently observed in malignant than in simple disease. The cause of it is difficult to determine. In some cases, as in those of Mikulicz, it is apparently due to spur-formation at the new orifice, of such a kind as to determine the flow of the intestinal contents into the stomach rather than in the reverse direction. At times the vomiting is trivial, occurring but once or twice, at times again it is most serious and hastens or determines death. It may be dealt with most satisfactorily by lavage of the stomach, by propping the patient in the semi erect posture, by abstinence from feeding by the mouth, and by securing a free action of the bowels, occasionally it will be relieved by allowing the patient to drink freely of milk or some other fluid. The vomit in the beginning is in appearance chiefly composed of bile and it is to the presence of bile in the stomach that the vomiting was attributed Riegel, Malbranc, and Weil have related cases where a reflux of bile into the stomach resulted in grave symptoms. Billroth remarked upon the serious import of the regurgitation of bile after gastro enterostomy Claude Bernard and others, founding their opinion upon laboratory work, considered that bile inhibited gastric digestion. Dastre, in dogs with gastric fistulæ introduced bile at all stages of digestion and concluded that the alkalinising effect of the bile was swiftly negatived by a copious outflow of gastric juice. No ill effects were noticed either in the digestive powers or in the general health. Oddi, experimenting upon dogs, obliterated the common bile duct and united the gall-bladder into the stomach. All the bile consequently flowed at once into the stomach, with the result that the animals gained in weight and suffered not at all. Max Wickhoff, Angelberger, and Terrier have performed cholecysto-gastrostomy successfully for obstruction in the common bile duct. These observations all show that the mere presence of bile alone is insufficient to induce vomiting Chlumskij has suggested that it is the presence of pancreatic juice which so irritates the stomach as to make it reject all fluids But this cause is negatived by Stendel s experiments upon dogs and by Moynihan's case,[2] in which owing to a complete severance of the gut at the duodeno-jejunal junction the duodenum was stitched up completely and the open end of the jejunum was implanted in the anterior wall of the stomach. In this case all the bile and all the pancreatic juice passed into the stomach, yet digestion was active and complete and vomiting was absent. Moreover Hartmann and Soupault have recently shown that in all cases of gastro-enterostomy, whether anterior or posterior, there is a reflux of bile and of pancreatic juice into the stomach, Carle and Fantino, Hayem Mathieu and others, have made the same observation. The cause, then, of regurgitant vomiting is not fully understood. My own view is that regurgitant vomiting is dependent on obstruction to the passage onwards of the intestinal contents either due to kinking or paralysis of the anastomosed jejunal loop or later to adhesions interfering with the regular vermicular contraction of the bowels. The case related below seems to me to prove the hypothesis.

CASE 1.—A single woman aged 28 years, was sent to me by Dr W—— on Dec 12th, 1901, with a history of pain after food and vomiting of three years duration, the weight having diminished from nine stones to six stones. When I saw her she could only take sips of milk and water and had constant epigastric pain There was also coffee ground vomit The outline of the stomach on distension with CO_2 was hour glass in shape and there was marked epigastric tenderness. After a gastro-enterostomy she lost her pain and gained weight, but three months later I had a letter to say that she had daily vomiting of bile in large quantity and though she could take food it did not nourish her In June the regurgitant vomiting was so troublesome that I admitted her to Leeds Infirmary for observation and after a few days opened the abdomen to find a band of lymph passing from the transverse mesocolon across the distal loop of jejunum and so constricting it as to produce obstruction. The fistula between the stomach and jejunum was fully patent and had not contracted in the least. The constricting band was divided and in order to make the result more certain the two arms of the jejunal loop were connected by a bone bobbin about three inches away from the stomach fistula Recovery was uninterrupted, the vomiting ceased entirely, and she returned home within the month well and able to take normal food. The improvement has continued and the patient is now well.

---

[1] Archiv fur klinische Chirurgie, Band lxii.

[2] Brit Med Jour May 1901

Several "complementary operations" have been suggested in order to prevent regurgitant vomiting Roux and Doyen cut the intestine across implant the distal end into the stomach and the proximal into the side of the distal, and thus avoid the "circulus vitiosus" Jaboulay, Braun, and Weir advise a side to side approximation of the proximal and distal loops

2 Subsequent contraction of the new orifice between the stomach and intestine must occur to some extent in all cases when the dilatation of the stomach present at the operation undergoes progressive diminution. Moynihan has recorded one case in which he performed a second operation because of closure of the orifice made with the help of Laplace's forceps and has operated upon another in which a colleague had three years previously performed gastro jejunostomy with the aid of Murphy's button. In this latter case the opening had completely closed Czerny records a case where the Murphy button was used in which the opening narrowed from a diameter of five centimetres to eight millimetres. As bearing on the closure of an anastomotic opening I have found the opening in a cholecyst-enterostomy made by a Murphy button to be closed three months later My colleague, Mr W H. Brown, related[3] a case of closure of an anastomotic opening in which Senn's plates were used in a woman, 62 years of age, for pyloric stenosis due to tumour, a recurrence of symptoms occurring a fortnight after the original operation. An exploration through a gastrotomy incision showed the opening to be closed by a membrane which the operator tore through with his finger, the ultimate result being excellent. After the employment of my bone bobbin I have never known the opening to close and in cases where months or years later I have had an opportunity of examining the site of the former operation I have always found the opening to be thoroughly patent and the passage through it to be smoothly lined with mucous membrane.

3. Pneumonia or pleurisy is said to have followed operations on the stomach with greater frequency than other operations on the abdomen, the reason given being the fixation of the ribs and the consequent difficulty in expanding the lungs subsequently to operation. My experience does not bear out this, for I have not found chest ailments to follow after operations on the stomach with greater frequency than is the case after any other major operation.

4 Cases of peptic ulcer in the jejunum after gastro-enterostomy are recorded by Braun, Halm, Kausch, Korte, Steinthal, Hadra, and Neumann In four cases the ulcer perforated and proved fatal. All the operations were performed when hyperchlorhydria was marked and persistent Under such conditions Neumann suggests that the operation of jejunostomy should be performed. The opening made in the bowel can be closed as soon as the gastric juice has returned to its normal condition[4]

5 Adhesions subsequent to gastro-enterostomy causing intestinal obstruction are probably uncommon, but Case 1 shows that they must be taken into account occasionally

6 A want of union in the newly joined viscera is an accident of a very serious and probably almost universally fatal character that used to be less rare when only moribund patients were operated on, but which is now seldom seen except when the Murphy button has been used, in which case there is nothing to prevent extravasation if union be delayed beyond the first few days, whereas when the union is effected by a double line of sutures delayed union if not too prolonged is not serious I have only seen the complication on one occasion in recent years and that was after the use of the metal button. Dr W Mayo in a paper in the *Annals of Surgery* for August, 1902, speaks of having had two fatal cases from separation of the anastomotic openings, one on the seventh day in malignant disease and one on the ninth day following an epileptic seizure, in both the Murphy button had been employed.

7 Passage of small intestine through the loop formed by the junction of the jejunum and stomach is probably only possible, certainly only probable, after the anterior operation, and the only case that I know of was one reported by Dr Mayo in the paper referred to which occurred in his hands a year after an anterior gastro enterostomy

Conditions subsequent to operation —Fantino[5] examined Carle's cases of gastro-enterostomy as regards the following points (1) changes in the peristalsis of the stomach, (2) the ability or non ability of the new sphincters to close the outlet, (3) the capacity of the stomach, and (4) the secretion of hydrochloric acid.

In the cases examined the operation immediately improved the peristaltic power of the stomach, though it did not render it normal The stomach could generally empty itself, but did so gradually Systematic examinations of the stomach contents were made after test-meals, &c, and showed that after an irregular period the stomach regained completely its power of emptying itself, in fact, as a rule, after gastro enterostomy the stomach would be found practically empty in from three to five hours after a meal. Generally it was found that the stomach decreased in size soon after gastro-enterostomy, so that the formerly distended organ became normal in size Examination of the stomach by mean of distension with carbonic acid and by other methods showed that a sphincter was developed at the new opening and that its power increased with time. The secretion of hydrochloric acid after operation was studied In cases where there was formerly hyperacidity this condition was lost, and though the degree of acidity in an individual case varied from time to time, yet these variations did not depart from physiological limits In the same examinations it was found that regurgitation of bile into the stomach took place, but it was of no importance so long as the outlet from the organ was sufficient. Cases of hypo and an acidity showed no change in their gastric juice after operation, showing clearly that this condition is not dependent on obstruction but on previous changes in the mucous membranes, these changes being probably in the nature of an atrophy of the peptogastric glands.

Changes in the stomach —If dilatation as the result of obstruction has been present before the gastro-enterostomy a certain lessening in the size of the stomach may be expected to occur as soon as a fresh outlet is formed The extent of this lessening depends entirely upon the condition of the muscular tunic of the stomach If the stomach has dilated gradually during many months or years and if the dilatation has been extreme there will be little or no rebound—the dilatation will undergo little or no perceptible diminution On the other hand, if dilatation has been rapid in its oncoming and has never attained a supreme degree the return to the normal size of the stomach will be almost, or wholly, complete In cancer of the stomach or in injury resulting from swallowing acids, &c., where the latter conditions are fulfilled the stomach rapidly lessens in size after operation, in simple stenosis, where the former conditions are found, the return is always trivial if, indeed, there be any lessening at all The motor insufficiency of the stomach is, according to Hartmann and Soupault, a permanent matter A return to the normal was never observed in any of their cases, even when the examination was made after one year Gastric digestion is prolonged beyond the normal limits. Mintz and Rosenheim have shown that there is a marked delay in the evacuation of the stomach contents. Carle and Fantino, on the other hand, assert that the emptying of the stomach after a full meal is not only accomplished within the period of physiological limit but is actually accelerated They add "This is often observed immediately after the operation and almost, or almost always, in the months that follow"

When the stomach is very largely dilated and the duodenum is mobile it is possible to short-circuit the pylorus by uniting the stomach to the duodenum The operation was suggested by Jaboulay in 1892 and has been performed by several surgeons with success. It can be performed with very little disturbance or exposure of viscera, but where the pyloric region is extensively diseased or adherent the operation is impracticable. The advantages claimed for it are that the new orifice or outlet from the stomach is near its natural place and that being placed above the biliary papilla there is no danger of regurgitation of bile The incisions into the viscera are both vertical and any one of the three methods of union can be employed.

[5] Archiv für Klinische Chirurgie, Band xlvi S 1 and 2.

have found the bone bobbin in this position to be quite simple of application.

The different indications for gastro-enterostomy cannot be stated in one category, for while in the first series the indications with certain provisos are absolute so soon as the diagnosis is established in the second series the indications for the operation apply only after failure of general treatment In the first series are—(1) simple stenosis of the pylorus, (2) malignant stenosis of the pylorus, (3) congenital stenosis, (4) congenital atresia, (5) chronic gastric ulcer with tumour of doubtful character too extensive or adherent for effectual removal, not necessarily associated with stenosis, (6) duodenal cancer or tumour causing obstructive symptoms, (7) hour glass contraction of the stomach not favourable for gastroplasty, (8) perigastritis with adhesions around the pylorus producing obstructive symptoms or pain and too extensive for gastrolysis, and (9) dilatation of the stomach dependent on pressure outside the pylorus from tumour of pancreas, liver, or gall bladder incapable of removal. In the second series after failure of medical treatment are—(10) acute or chronic gastric ulcer, (11) duodenal ulcer, (12) hæmorrhage from gastric or duodenal ulcer, (13) persistent spasm of pylorus or Reichmann's disease with dilatation of the stomach, (14) hyperchlorhydria (15) persistent gastralgia, (16) tetany of gastric origin, (17) acute gastric dilatation not yielding to lavage and general treatment, (18) pancreatitis secondary to gastric ulcer, (19) certain cases of jaundice dependent on gastric or duodenal ulcer leading to thickening around the common bile-duct, and (20) simple atonic dilatation of the stomach after failure of lavage and general treatment. Although I have performed gastro-enterostomy for nearly all the conditions here mentioned and could give numerous examples in illustration, yet it is clearly impracticable in one lecture to do more than to refer briefly to some of the indications

1 In cases of pyloric stenosis leading to dilatation of the stomach gastro-enterostomy provides a new opening for the passage of the stomach contents and thus saves the patient from starvation and death. If the stenosis be due to simple ulcer and the pylorus is free from adhesions the question will arise as to whether pyloroplasty should be performed for it can be done quickly with very little exposure of viscera and I have myself performed it on many occasions with excellent results, but the fact that occasionally contraction of the new orifice occurs, especially if there is active ulceration going on at the time of operation, has led me to favour gastro-enterostomy The following case serves as an example of relapse following on pyloroplasty for stenosis with subsequent success by gastro-enterostomy

CASE 2.—The patient, a married woman, aged 29 years was seen with Dr S—— on March 9th, 1895 A history was given of pain in the epigastrium for ten years with exacerbations and so-called spasms two or three times a week, the attacks lasting from two to 24 hours and being relieved by vomiting Severe tetanic cramps in the legs were complained of and there was obstinate constipation. The stomach was markedly dilated, but no tumour could be felt. The right rectus was rigid, and tenderness was well marked over the pyloric region and towards the left costal margin. There had been a loss of weight to the extent of two stones and the patient was unable to perform her household duties Operation was performed on Nov 22nd The pylorus was found to be stenosed and surrounded by adhesions. The adhesions were separated and pyloroplasty was performed, the patient making a good recovery and gaining weight and strength. She was seen in July of the following year, when, though there was some complaint of indigestion the vomiting had not recurred and she was half a stone heavier than when operated on in November After this date the symptoms of obstruction at the pylorus returned, and on Sept. 4th, 1898, gastro-enterostomy was performed A good recovery ensued and the patient has remained well, having fully regained her lost weight and strength and being now, four years later in good health.

The following three out of many similar cases are good examples of simple pyloric stenosis treated by gastro-enterostomy

CASE 3.—The patient, a man aged 45 years was seen at the Leeds Infirmary He had suffered pain for two years with vomiting for nine months. Great dilatation of the stomach was present. There were thickening and puckering near the pylorus. On June 12th, 1900, exploratory gastrotomy was performed. A large chronic ulcer was discovered on the posterior wall as well as cicatricial stenosis of the pylorus Posterior gastro-enterostomy was performed. Complete restoration to health resulted and the patient was well in 1901

CASE 4.—The patient, a man, aged 28 years (who was seen with Dr G——), was suffering from pyloric ulcer with tumour of the pylorus. Two years previously his weight was 12 stones 12 pounds, now it was 9 stones 6 pounds He had pain two hours after food. For the last two months vomiting had been present on an average five times a week, and on two occasions the vomit was like coffee-grounds. There was enormous dilatation of the stomach The pyloric tumour was freely moveable. There was visible peristalsis. Operation was performed on August 4th, 1899 A large mass was found at the pylorus which was evidently thickening due to active ulceration. The glands were large but not matted. Gastro-enterostomy was performed on the 27th The patient made a good recovery and weighed 9 stones 7 pounds On Sept. 20th, 1899 his weight was 10 stones 13 pounds. He could eat anything He was well when seen in 1901.

CASE 5.—The patient a married woman, aged 38 years, who was seen with Dr M——, had suffered from indigestion for 20 years The pain was constant, lately it was present one and a half hours after taking food, it was easier when lying down. She had lost 1 stone 11 pounds in weight. Posterior gastro-enterostomy was performed on Jan 8th, 1901 Scars of ulcers were found on the pylorus and the anterior stomach wall. Stenosis of the pylorus was present as well as enlarged glands in the lesser omentum. Recovery ensued. Her weight was 6 stones 11 pounds at the time of operation, two months later it was 7 stones 9 pounds. She was quite well and of normal weight when she was seen in October, 1902.

2 The following cases serve to illustrate the beneficial effects of gastro-enterostomy in malignant stenosis of the pylorus incapable of removal and I would take this opportunity of stating that I differ *in toto* from the opinion expressed lately by an eminent London surgeon, who said "It is very doubtful if there is ever sufficient benefit to be derived from gastro-enterostomy and other short-circuiting operations in malignant disease to make it worth while undergoing these operations." Needless to say, wherever the glands are not extensively involved or there are no secondary growths the tumour should be completely removed In this class of case it might be expected that the mortality would be much higher than in simple disease and in my first series of cases that was so but later experience with the improved operation shows the immediate results to be almost equal to those of simple stenosis.

CASE 6.—The patient was a married woman, aged 37 years, who was seen with Dr D—— Cancer of the body of the stomach and pylorus with dilatation was diagnosed. Gastro-enterostomy was performed on Dec. 21st, 1899 She made a good recovery and was so well that gastrectomy was advised, but cancer of the uterus supervened and prevented further operation. She lived for nine months in comfort and was able to take ordinary food.

CASE 7.—The patient, a man, aged 63 years had symptoms for five years—at first those of chronic ulcer later those of malignant ulcer with tumour associated with hæmatemesis Gastro-enterostomy was performed on March 22nd, 1901. He made a good recovery He returned home at the end of the month and gained 4 pounds in weight during the fourth week. He ultimately gained about 2 stones and lived for a time in great comfort, but the growth progressed and he succumbed to exhaustion about a year later having been able to enjoy life for some months

The following is an example of cancer of the stomach where the patient was too ill for gastrectomy in which a rapidly performed gastro-enterostomy gave such relief that a subsequent radical operation was well borne.

CASE 8.—The patient a man, aged 63 years, was seen with Dr G—— of Burnley for stomachic symptoms of a year's duration a tumour having been noticed for a month. Gastro-enterostomy was performed on Nov 15th, 1900 A central ring of cancer was found dividing the stomach into two cavities The patient was too ill to bear gastrectomy A good recovery was made with a rapid gain in weight and strength, so that on Dec. 20th the complete removal of the growth by gastrectomy was well borne and when last heard of a year later he was at work and in good health

CASE 9.—The patient was a single woman, aged 24 years A history was given of ulcer of the stomach with frequent vomiting for five years, the vomit of late being coffee ground in character Great emaciation was present. She had been confined to bed for some months Her weight was only 4 stones 5 pounds The vomit contained free HCl, with blood and sarcinæ. A tumour in the epigastrium could be easily felt and seen Posterior gastro enterostomy was performed on April 17th, 1902 The tumour was adherent and presented every appearance of cancer, the anterior wall of the stomach was extensively involved, the glands being largely affected. The patient made a good recovery with a rapid gain in weight. Her medical adviser told me in October that the tumour had apparently disappeared and that she had gained 5 stones, thus more than doubling her weight within six months of the operation. It remains to be seen if this is a case that should come under simple tumour simulating cancer

3 A degree of congenital stenosis is doubtless a frequent, though often an unrecognised, cause of dilatation of the stomach in young adults Maier[6] recites a number of cases, mostly in adults, of chronic catarrh of the gastric mucous membrane with dilatation in which stenosis of the pylorus varying from three millimetres to one centimetre (the normal being from one to three centimetres) was found. This form of stenosis may explain many of the cases of dilatation and catarrh of the stomach coming on in young adults without apparent cause and it may also explain many of the cases of persistent vomiting set down to a vicious habit or to hysteria. To judge from the literature of the subject this condition is not of frequent occurrence but it may be more common than is supposed, as necropsies are not frequently made in the case of children dying out of hospital and persistent vomiting in infants is not a very uncommon event. The first successful operation in an infant was recorded by Abel in 1899 the patient being eight weeks old. Several other cases have since been reported In February, 1900, I operated on a young man, aged 24 years, for dilatation of the stomach in which the stenosis of the pylorus was probably a congenital defect, for the indigestion had existed since childhood, though much worse during the five years previous to my seeing him, yet there was no history of ulcer or other trouble to account for it and at the time of operation the pylorus would barely admit the tip of the little finger

4 Congenital atresia of the pylorus, in which no passage exists between the stomach and intestine, is a defect which in all recorded cases has run a rapidly fatal course If diagnosed early it should be treated by gastro-enterostomy

5 In chronic gastric ulcer with tumour of doubtful character too extensive or adherent for effectual removal. I have operated on quite a number of cases in which after a long history of stomach symptoms a tumour had developed which on external examination presented every appearance and the feel of cancer, and even when the abdomen was opened the tumour gave the same impressions, but any enlarged glands were discrete and there were usually adhesions which precluded any attempt at removal. The following cases serve to illustrate what I mean and to show that in some of these cases where merely temporary relief only was anticipated complete and permanent cure resulted from the operation.

Case 10 —The patient was a man, aged 31 years, who was seen with Dr B—— and Dr W—— He had had dyspepsia for 17 years, this had been more severe during the last 20 months 16 months previously vomiting began and from the outset large quantities were ejected but never contained blood. There was recurrence occasionally of similar attacks which were always relieved by treatment. In December, 1897 the stomach reached to the pubes and visible peristalsis was present Relief followed dieting and lavage until March, 1898 since which time the pain had been almost constant. The pain was not materially worse after food or relieved by vomiting A loss of weight occurred from 10 stones to 8 stones 6½ pounds There was great feebleness Gastro-enterostomy was performed on May 6th, 1898 A large irregular tumour was found at the pylorus and along the lesser curvature with extensive adhesions, but the glands, though large, were discrete. A good recovery was made, followed by relief of all the symptoms. When the patient left the home on June 7th his weight was 8 stones, on August 17th, 1898 it was 9 stones 3 pounds. The following is an extract from a letter received from the patient dated Feb 12th, 1900 ' My health continues perfect I have not lost a day's work through illness since I recovered." He was in good health in 1902.

Case 11.—The patient, a man, aged 45 years, gave a history of pain for two years about an hour after food, with great loss of flesh. For nine months he had vomited every day or every second day a large quantity of yeasty material, but no blood, though he was very anæmic There were well marked signs of dilatation of the stomach, with tenderness over the pylorus and the presence of a tumour Posterior gastro enterostomy was performed on June 12th, 1900 On opening the abdomen the pylorus was found to be much thickened and adherent, forming a hard nodular tumour having the appearance and feel of cancer Through the centre of the mass a No 10 catheter only could be passed over a roughened ulcerated surface An uninterrupted recovery followed. Food was begun the second day and solids could be taken in the second week without pain He rapidly gained flesh and strength and is now well

Case 12.—The patient, a man, aged 48 years, who was seen with Dr R——, was supposed to be suffering from cancer too advanced for treatment, the patient being extremely feeble and having lost from 2 to 3 stones in weight in six months The presence of a tumour in the pyloric region with well marked dilatation of the stomach and profuse coffee-ground vomiting rendered Dr R——'s diagnosis extremely probable, though the history of pain from one and a half to two hours after food for three years with other symptoms of pyloric ulcer led me to hope that the disease might be simple. Operation was performed on May 30th 1902. An extensive tumour at the pylorus associated with stenosis and dilatation of the stomach, with perigastritis and adhesions, together with numerous discrete though much enlarged glands, led me to perform gastro-enterostomy The patient rapidly put on weight, gained strength, and lost all his distressing symptoms. When he returned to report himself in three months he was robust and well and no trace could be found of the tumour or of the dilatation of the stomach He is to day in perfect health

These cases teach the important lesson that one ought not hastily to give a hopeless prognosis after gastro-enterostomy for tumour, for when there is any doubt whatever about the malignancy or otherwise of the growth it is well to give the patient the benefit that is derived from the hope of cure. Another lesson to be learnt is that an exploratory operation is worth performing in nearly all cases of tumour of the stomach, for even if the growth cannot be removed the rest engendered by a gastro-enterostomy will almost certainly give relief, and in some cases thought at first to be malignant a cure may be effected

6 In cancer or other tumour of the duodenum producing obstruction to the onward passage of the stomach contents gastro enterostomy acts exactly in the same manner as in cancer of the pylorus As a rule this form of disease in the second part of the duodenum is removeable only with the greatest difficulty, in consequence of the important structures in the border of the lesser omentum being involved.

I was once tempted to perform such an operation which involved my removing the vertical part of the duodenum, part of the head of the pancreas, and about one inch of the common bile-duct, the passage of bile having to be made good by the performance of cholecyst-enterostomy and of the stomach contents by gastro-enterostomy The patient promised to do well for some days, but leakage from the duodenum ultimately led to death from exhaustion. I shall in future be content with the performance of gastro-enterostomy alone, as in a case on which I operated recently there was a well marked tumour (probably inflammatory around a duodenal ulcer) which entirely disappeared after gastro enterostomy and the patient is now well

7 Hour glass contraction of the stomach may be due to chronic ulcer or to cancer If the contraction be due to simple ulceration, gastroplasty is the operation of choice and in a number of cases in which I have performed it the results have been excellent, but if the stricture be a long one and the thickening be very extensive, then gastro-enterostomy, in which the proximal cavity is united to the jejunum, is the better operation, as in the following cases, but great care must be observed that the junction is not made between the bowel and the distal cavity as in at least two cases that have been reported, otherwise no benefit will ensue. It should be the operation of choice when pyloric stenosis is associated with hour glass contraction

---

[6] Virchow's Archiv Band cli.

CASE 13.—The patient, a man, aged 52 years, who was seen with Dr. H——, gave a history of pain vomiting, and loss of weight and strength for three years. Epigastric tenderness was well marked. Posterior gastro-enterostomy was performed on Oct. 12th, 1900 Hour glass stomach was found, though the stricture was not extreme. The cardiac complement was also dilated. Recovery ensued. On March 4th, 1901, I received a letter to say that the patient's weight was 9 stones 11 pounds and that he was in good health. At the time of operation his weight was 8 stones 6 pounds.

CASE 14.—The patient was a man who gave a history of stomach symptoms for three years. In one attack perforation occurred Posterior gastro-enterostomy was performed on Nov 15th, 1900 Strong adhesions to the liver and colon were found The stomach was contracted in the centre The patient made a good recovery and when heard of subsequently he was in very good health.

Should the hour glass condition be due to a circular mass of growth constricting the centre of the stomach the proximal cavity may be advantageously fixed to the jejunum, and if by good chance the growth be limited, the glands be not enlarged and there be no secondary nodules the mass of growth may be subsequently removed as in a case previously related

8. In perigastritis with adhesions the operation of gastrolysis may be entirely curative as in many cases that I have operated on, but there are some cases where the adhesions are so extensive and the secondary dilatation of the stomach is so well marked that to rest content with simply detaching adhesions would be to court failure. If the pylorus is patent yet embarrassed by adhesions, I always separate them, and try to avoid their recurrence by interposing the right free border of the omentum between the raw surfaces left by the gastrolysis thus substituting a long, freely moveable attachment for short binding ligaments should adhesions re form. If, however, adhesions are very extensive and very short, dense, and firm, the operation of posterior gastro-enterostomy had better be done and this especially if at the same time there is stenosis of the pylorus or an hour glass stomach. In December 1900, I saw a woman, aged 57 years suffering from constant pain at the epigastrium intensified by food so that she was unable to take any solids, and as she had been unrelieved by general and medical treatment I operated and found the anterior wall of the stomach adherent to the abdominal wall and to the liver The extensive adhesions were detached and a posterior gastro-enterostomy was performed with the result that she was entirely relieved of her distressing symptoms and has remained well.

9. In tumour outside the pylorus but pressing on it and causing obstruction to the passage onward of the stomach contents gastro-enterostomy may be required at the same time that the tumour is treated The following is a case in which a pancreatic cyst was drained and gastro-enterostomy was performed at the same time

CASE 15.—A man, aged 35 years after a history of ulcer of the stomach for four years associated with pain an hour after food and with vomiting and great loss of weight, was sent to me by Dr G—— who had tried medical treatment most thoroughly with only temporary relief The patient's weight had gone down from 170 to 130 pounds From the history of the pain being relieved when the patient turned into the prone position and the fulness felt behind the stomach in the region of the pancreas together with slight jaundice it was suspected that the ulceration was in the posterior wall and that the pancreas was becoming involved. Gastro-enterostomy was advised but declined. The patient returned two months later in the last stage of exhaustion and with all the stomach symptoms more marked, the stomach being now greatly dilated, here was now a tense fluctuating tumour occupying all the epigastric region and extending well over to the right side which was diagnosed as a pancreatic cyst. Anterior gastro-enterostomy was performed on June 10th 1902. A large pancreatic cyst was exposed containing four pints of grumous fluid. This was tapped through the great omentum and then drained, the tube being fixed in the cyst by a purse string suture so as to make the opening embrace the tube tightly and prevent leakage. The posterior wall of the stomach and the pylorus were found to be fixed to the pancreas. The patient made a steady recovery and rapidly put on flesh All stomach symptoms disappeared and he was able to return home within the month looking and feeling well. Though the fluid collected in the pancreatic cyst three months later it caused no return of stomach symptoms and the insertion of a tube soon effected relief of the tumour which is still being drained.

The following indications apply only after failure of systematic medical treatment.

10. In ulcer of the stomach, whether acute or chronic, not yielding to medical treatment surgical treatment is in the greater number of cases the only satisfactory method of dealing with these refractory cases and operation should be resorted to at a much earlier period than has hitherto been the custom and always before the patient is so far reduced by pain and starvation or the supervention of serious complications that weakness and anæmia render any operative procedure hazardous Before the abdomen is opened it is quite impossible to say what operation or operations will be required and the surgeon must be prepared to adapt himself to circumstances on discovering the position of the ulcer and the conditions associated with it especially as to the presence or absence of adhesions and other complications The following case, one out of many on which I have operated, serves to show the beneficial effects following on gastro-enterostomy in intractable gastric ulcer. It acts by securing physiological rest of the stomach and at the same time curing the hyperchlorhydria which is usually present

CASE 16.—The patient, a single woman aged 32 years, seen with Dr. A——, gave a history of stomach symptoms extending over several years She had had hæmatemesis in 1892 and 1896, since which time she had suffered from flatulence and pain after food For two years epigastric pain had been constant but increased by food. For a year she had vomited daily and for some months only milk in small amounts could be retained. Epigastric tenderness was well marked and on distending the stomach with CO_2 it reached half an inch below the umbilicus and far over to the right of the middle line. Posterior gastro-enterostomy was performed on Oct. 5th, 1900 The patient returned home within the month, taking solid food without any discomfort and gaining flesh On Nov 8th Dr A—— wrote "I have seen Miss —— since her return and there is every reason to be pleased with her condition She has lost all her pain and is taking food well Allow me to thank you for her restoration to health " Her weight in February, 1901, was 8 stones 6 pounds, at the time of the operation it was 6 stones 12 pounds.

11. Duodenal ulcer very frequently fails to yield to general treatment and from the experience I have had of these cases I believe it is much more frequently the cause of fatal symptoms than is generally recognised I hope to report a series of cases of duodenal ulcer treated by gastro-enterostomy on a future occasion.

12. In hæmorrhage from the stomach or duodenum as shown by hæmatemesis or melæna, where general treatment has been tried and failed and where the bleeding is persisting or recurring after brief intervals operation is advisable with a view to find and to secure, if possible the bleeding point or points or of performing gastro-enterostomy in order to obtain physiological rest and thus to favour natural hæmostasis

I have been asked to open a discussion on the surgical treatment of hæmatemesis at the Medical Society of London in December I need therefore not dwell on it now

13. In persistent spasm of the pylorus or Reichmann's disease, leading to dilatation of the stomach, pylorodiosis or stretching the sphincter may be effectual in relieving spasm and in producing immediate relief to the obstruction, but as it is apt to be followed by relapse I have given up performing the operation, in favour of gastro-enterostomy

Not feeling satisfied with the calibre of the pylorus in one case after I had stretched it as far as I thought safe, I immediately performed pyloroplasty The condition then revealed showed me the cause of relapse for I found two rather extensive lacerations through the mucous membrane quite into the substance of the pylorus. As these lacerations would have had to heal under the unfavourable condition of being constantly irritated by food and the acid contents of the stomach there must have been a considerable effusion of plastic lymph which would inevitably have led to cicatricial contraction and so to stenosis This, I suspect, occurs in all cases where the pylorus is fully stretched and explains my reason for having no faith in Loreta's operation.

14 Hyperchlorhydria is a regular concomitant of ulcer of the stomach though it may occur apart from ulceration. As a rule it yields to medical and general treatment, but where such treatment fails to relieve and the life of the patient is being made miserable by constant indigestion with acid

eructations the operation of gastro-enterostomy is well worth consideration, especially when in such a case it can be performed with almost no risk, for in the absence of complications such as occur in ulcer and cancer the operation when properly performed by an expert ought to have no mortality

15 *Persistent gastralgia* —Cases must have occurred in the practice of every physician where although the positive signs of ulcer were absent, gastralgia of such intensity has persisted, and in case of temporary relief has recurred so regularly, that the patient is brought to the last stage of exhaustion by an utter inability to take food because of the pain induced by even a mouthful of solid. Some of these cases are doubtless due to simple ulcer, but in others the absence of tenderness in the epigastrium, of rigidity of the recti, of regular vomiting, and of hæmatemesis makes the diagnosis extremely doubtful. Even rectal feeding and absolute rest in bed do not always cure the condition and the patient gradually loses weight and strength and lapses into a state of chronic invalidism without any positive sign of organic disease. After all ordinary means have failed gastro enterostomy is well worthy of consideration, and, as the following case will show, it may lead to excellent results

Case 17 —The patient was a single woman, aged 27 years, who was seen at the Leeds Infirmary She had suffered from pain and indigestion since she was a girl, vomiting occurred at times, though she never brought up blood. The stomach was dilated and tender Free HCl was found in the contents of the stomach. She had lost weight and weighed now 7 stones 6 pounds Gastro-enterostomy was performed on March 7th, 1901. No scarring or other signs of ulcer were discovered. Soft solids were allowed at the end of the month The patient made a good recovery and was able to take food without pain, ultimately she was completely restored to health

16 In tetany of gastric origin The prognosis of tetany occurring in gastric dilatation is undoubtedly very serious, and according to some authorities death occurs in nearly 75 per cent of the cases The largest mortality occurs in cases where the spasm in the extremities is associated with tonic spasms in the head and trunk muscles or with clonic spasm. My own experience of tetany and of the severe muscular spasms in association with gastric dilatation leads me to think that we may possibly take a more hopeful view if the cases be treated surgically at an early period. The following case will serve to illustrate my views.

Case 18 —A man, aged 34 years was sent to me by his medical attendant in January, 1895, with a view to have something done in the Leeds Infirmary to relieve his condition. He had been suffering for five years from pain after the ingestion of food, with attacks of vomiting Latterly his condition had become aggravated, the pains occurring from half an hour to one hour after each meal and being relieved only by vomiting, so that for the last six months he had had to give up his work as a printer For some time before coming under my notice there had been very evident peristalsis from left to right in the epigastric region. Throughout the period over which his stomach symptoms extended his bowels had for the most part been very constipated but there were occasional attacks of diarrhœa. During this time he had attacks of what he described as "cramps" in his limbs and especially in his legs. He had lost very considerably in weight, as in December 1892 he weighed 9 stones 7½ pounds. On examination there was found well marked dilatation of the stomach, but the feature of the case which presented most interest in connexion with the present question was the occurrence while under observation of severe tetanic spasms affecting almost all the muscles of the body So extreme and so widespread were these, the muscles of the trunk and of the cervical region as well as those of the limbs being affected, that on Jan. 17th the question of possible strychnine poisoning was raised As palliative treatment of the stomach condition gave no relief the stomach was exposed on the 24th and the diagnosis of cicatricial stenosis with hypertrophy of the pylorus was confirmed. Pyloroplasty was performed, a bone bobbin being employed to insure patency of the new pylorus. Recovery was uninterrupted and although the cramps were present up to the time of operation he never had a threatening of cramp afterwards. On Feb 15th he was able to take a mutton chop for his dinner without inconvenience and by March 2nd (five weeks after the operation) he had gained 8 pounds. Two years after the operation he had quite recovered his strength and was working as usual, his weight then being just over what it was in December, 1892, and quite 2 stones above what it was at the time of the operation. There had been no recurrence of "cramps" or of muscular spasms of any kind. In a letter received at the beginning of 1899 he speaks of some stomach disorder, but he adds "You will please understand that I am a new man to what I was when you saw me last." A recurrence of stenosis necessitated gastro-enterostomy, which I performed early in 1902, but it is interesting to note that on this occasion, though he was much wasted and was vomiting every day, there was no return of the tetany He made a good recovery and is now well and strong again

17 Acute gastric dilatation is one of the most serious diseases that can be encountered. It was first described by the late Dr Fagge, his paper being illustrated by two cases, both in men, 30 and 31 years of age respectively, and both ending fatally In the Leeds Infirmary during the past ten years there have been at least four fatal cases But that the condition of acute gastric dilatation is not hopeless the following case distinctly proves.

Case 19 —A woman, aged 35 years, who was under my care, recovering smoothly from cholecystotomy which had been performed a week previously, was suddenly seized with pain in the epigastrium, followed by vomiting, which soon became ineffectual in emptying the stomach. Rapid dilatation ensued and the stomach not only formed a large swelling filling up the superior abdominal region but also extended well below the umbilicus towards the pubes. This, owing to pressure on the diaphragm, and through it to pressure on the heart and lungs, led to great shock, quick and oppressed breathing, and a rapid, feeble pulse, with signs of lividity and imperfect aeration of the blood. The urine was scanty and, in fact was almost suppressed. Strychnine was freely administered subcutaneously, but no relief followed until the stomach tube was used when a large quantity of gas and several pints of brownish fluid were evacuated, the lavage was repeated several times during the next two days, during which time alimentation was entirely rectal. It is interesting to note that the pulse and temperature were paradoxical, the former running up to 150 and the latter down to 97 3° F All the symptoms passed off under treatment almost as quickly as they came and in a week the stomach had returned to the normal size

I would suggest that in every case of this kind where stomach lavage has failed, but only then (for the stomach tube is the first indication, no matter at what stage it may be recognised, unless, indeed, the patient be actually dying), the abdomen should be opened and the stomach should be emptied and connected with the jejunum, thus providing for continuous drainage into the intestine I believe that as yet gastro-enterostomy for acute dilatation has not been put to the test

18 In an exceptional case of ulcer of the stomach eroding the pancreas and producing pancreatitis with abscess draining into the stomach, a gastro-enterostomy apparently saved the life of the patient by draining the very foul contents directly into the intestine. The case is reported in "Diseases of the Stomach and their Surgical Treatment," p 168, so that I need not repeat the account here

19 Cholelithiasis may lead to perigastritis and the contraction of bands of lymph around the pylorus may produce obstruction or kinking, thus leading to dilatation of the stomach at the same time that the concretions lead to obstruction of the bile-ducts. As a rule the condition can be relieved by gastrolysis, but where the adhesions are extensive or the thickening of the pylorus is very pronounced the operation of gastro-enterostomy may have to be performed at the same time as the cholecystotomy Gall stones may also lead to fistula between the gall bladder and pylorus and the thickening of the pyloric canal may lead to obstruction, for which gastro-enterostomy may be the most suitable operation, though in the cases that have come under my care the repair of the fistula in one case and pyloroplasty in another were sufficient when combined with cholecystotomy to remedy the disease

20 In atonic dilatation of the stomach general and medical treatment, supplemented, if need be, by electrical treatment and lavage, if carried out systematically and for a sufficient length of time, usually yield good results, but in some cases, despite regular lavage of the dilated organ, well regulated diet, and general medical treatment the dilatation persists and the nutrition of the patient and the general health become seriously impaired. In such cases

the operation of gastrorrhaphy or gastroplication may be worth considering, though in certain cases gastro-enterostomy may possibly be performed with advantage The indication for operation in these cases is not so distinct as in the cases of dilatation due to pyloric obstruction, seeing that the cause is a general one, nor is the recovery after operation so rapid and satisfactory The general health requires considerable attention at the same time that the stomach is being dealt with

I fear that you may think that I have made out a very formidable list of conditions suitable for relief by gastro-enterostomy, but I trust that the cases which I have related as examples will serve to show that I have not exaggerated the importance of my subject.

In conclusion I would say that if the procedure is to hold its own as one of the most beneficial operations in surgery it must continue to be done with a very small mortality, which will be effected only by observing every care in detail before, at the time of, and subsequently to, operation.

LUNACY AND THE LAW[1]

BY T OUTTERSON WOOD, M.D DURH, F R.C P EDIN, M.R.C P LOND,

SENIOR PHYSICIAN TO THE WEST-END HOSPITAL FOR NERVOUS DISEASES, EPILEPSY AND PARALYSIS

IT augurs well for the success of the action taken by the conjoint committee of the British Medical Association and the Medico-Psychological Association with regard to the amendment of the Lunacy Law to enable cases of recent (incipient) insanity to be legally treated in private care without being certified as lunatics, that the Lord Chancellor inserted into his proposed Lunacy Bill a clause to meet our requirements in the very terms which I advocated at the annual meeting of the British Medical Association in 1896 The importance of the subject must be my justification for bringing before this association some features in connexion with it from a practical point of view I look upon the question for my present purpose as being divided into two sections only, for I intentionally leave the rate aided class to be dealt with elsewhere.

Section 1 —The proposal to extend the provisions of the present law so that incipient cases of mental disorder may legally and without delay be brought under care and treatment without certification, and

Section 2 —The suggestion that cases admittedly certifiable, or even already certified, may be placed in single care without the so-called stigma of certificates, or if already admitted into an asylum, they may be taken out and placed in the house of some relative or impecunious person and kept there for profit, and not necessarily for cure, for it is not suggested that these patients may be curable

Now, with regard to the first section which deals with cases of recent—i.e., incipient—insanity I would divide them into two classes—(1) those who are amenable to reason and advice, who are absolutely uncertifiable, and who can to a great extent take care of themselves, and (2) those recent cases of a mild type in which the mental warp is more pronounced, who may require removal from home, who are almost certifiable or who may even have harmless delusions, who require a certain amount of moral restraint, and who may object to the control necessary for their proper treatment. With regard to Class 1, no alteration in the law is necessary, these patients are as capable of treatment outside the Lunacy Law as any ordinary medical case. I have to deal with a large number of them as out-patients at the hospital and I have no difficulty whatever with them. It is with regard to Class 2 that the law requires amendment to enable us to obtain the legal control of the patient, and a system of notification seems to me the best to meet the requirements of such cases. This, however is no new idea. I have for years advocated a relaxation of the present law in order that incipient, doubtful, or undeveloped cases might under suitable conditions and at the earliest moment be brought under that expert care and treatment which experienced alienist physicians know to be so necessary for the arrest of the disorder and the cure of the patient. Upon this point I am glad to think we are all agreed. It is the adoption of a principle that has worked well in Scotland for many years and I know of no reason why, under proper conditions and with the necessary safeguards of skilled supervision, it should not work equally well in England and Wales, the order of a magistrate on this side of the border taking the place of the order of the sheriff as in Scotland for the legal detention of the patient for a definite period. There is, however, one point upon which we must insist and it is that wherever these cases are so placed, whether it be in a medical man's house or not, they shall be at once notified to the Commissioners and be placed under their official supervision as well as that of some skilled and independent local authority appointed by the Lunacy Board. Above all, we must be certain that it shall not be merely a matter of boarding them out in so-called medical homes or private houses kept by unqualified, inexperienced, and untrained persons, but that we shall have some guarantee that they will be cared for and looked after by those who have been trained in some recognised institution for the insane or whose competence is assured by long experience and who shall be approved of by the Commissioners, and, further, that they shall be nursed and attended not by hospital nurses who have had no asylum training but that their nurses shall be asylum trained and, preferably, that they shall hold the certificate of the Medico-Psychological Association for proficiency in nursing and caring for those of unsound mind.

It is absurd to imagine for one moment that such cases as these can be properly treated by persons with no special knowledge of, or experience in, all the details of the moral control that these persons require and we must speak out with no uncertain voice in our condemnation of any attempt to minimise this the most vital part of their treatment. The periodic visits of a consultant are practically useless as regards the supervision of these details, which are of daily, even hourly, importance for the cure of the patient. This of course, we cannot expect physicians, however eminent, to appreciate who have not made a special study of the care and treatment of mental disorders It is the absence of this special knowledge on the part of the hospital physician which will permit him, on the one hand, to give these, the most difficult of all cases to manage, into the care of inexperienced people of limited means, or hospital nurses with no asylum training, who do not know what to do with them, who cannot understand the constant supervision and the unceasing vigilance which they require, who are unable to anticipate a suicidal impulse or an outbreak of homicidal violence, and who will either rush in terror from the room at an outburst of excitement or will resort to the injudicious and unnecessary use of mechanical restraint, or, on the other hand, to give them up to the tender mercies of the keeper of some medical home or nursing institution who has never seen the inside of an asylum and who does not hesitate to send out hospital trained nurses to acute mental cases and untrained domestic servants as trained mental nurses. I am speaking of things of which I have personal knowledge and in my opinion instead of the law being made more elastic with regard to these transparent frauds it should step in and compel every nursing home or institution receiving such cases as these to be placed under some official supervision. If this were done we should hear less of the fatalities which are of such frequent occurrence and which help to fill the columns of the daily press. While, therefore, we advocate the early treatment of cases of incipient insanity without certificates let us endeavour to make sure it will be carried out in such an efficient manner that there shall be no excuse in future for the smuggling away of what are termed "borderland" cases or those deliberate evasions of the law which have been alluded to, and even boasted of, before the members of this law abiding association and which have in so many instances been followed by fatal results

I will now turn to the second section of the subject—I mean the suggested extension of this system of notification for incipient cases so as to make it applicable to chronic certifiable cases of insanity and to those already certified and living in institutions for the insane. This, in my opinion, would be a dangerous innovation. It is sad to reflect that at this time of day we are compelled to reiterate the arguments of our predecessors in this association against the unwisdom of such a retrograde step and that the cruelties of mechanical restraint must again be brought forward to steady eructations the operation of gastro-enterostomy is well worth consideration, especially when in such a case it can be performed with almost no risk, for in the absence of complications such as occur in ulcer and cancer the operation when properly performed by an expert ought to have no mortality.

---

[1] A paper read before a general meeting of the Medico-Psychological Association held at the County Asylum, Mickleover, near Derby on Feb 12th, 1903,

15. *Persistent gastralgia.*—Cases must have occurred in the practice of every physician where although the positive signs of ulcer were absent, gastralgia of such intensity has persisted, and in case of temporary relief has recurred so regularly, that the patient is brought to the last stage of exhaustion by an utter inability to take food because of the pain induced by even a mouthful of solid. Some of these cases are doubtless due to simple ulcer, but in others the absence of tenderness in the epigastrium, of rigidity of the recti, of regular vomiting, and of hæmatemesis makes the diagnosis extremely doubtful. Even rectal feeding and absolute rest in bed do not always cure the condition and the patient gradually loses weight and strength and lapses into a state of chronic invalidism without any positive sign of organic disease. After all ordinary means have failed gastro enterostomy is well worthy of consideration, and, as the following case will show, it may lead to excellent results.

CASE 17.—The patient was a single woman, aged 27 years, who was seen at the Leeds Infirmary. She had suffered from pain and indigestion since she was a girl, vomiting occurred at times, though she never brought up blood. The stomach was dilated and tender. Free HCl was found in the contents of the stomach. She had lost weight and weighed now 7 stones 6 pounds. Gastro-enterostomy was performed on March 7th, 1901. No scarring or other signs of ulcer were discovered. Soft solids were allowed at the end of the month. The patient made a good recovery and was able to take food without pain, ultimately she was completely restored to health.

16. In tetany of gastric origin. The prognosis of tetany occurring in gastric dilatation is undoubtedly very serious, and according to some authorities death occurs in nearly 75 per cent of the cases. The largest mortality occurs in cases where the spasm in the extremities is associated with tonic spasms in the head and trunk muscles or with clonic spasm. My own experience of tetany and of the severe muscular spasms in association with gastric dilatation leads me to think that we may possibly take a more hopeful view if the cases be treated surgically at an early period. The following case will serve to illustrate my views.

CASE 18.—A man, aged 34 years was sent to me by his medical attendant in January 1895, with a view to have something done in the Leeds Infirmary to relieve his condition. He had been suffering for five years from pain after the ingestion of food, with attacks of vomiting. Latterly his condition had become aggravated, the pains occurring from half an hour to one hour after each meal and being relieved only by vomiting, so that for the last six months he had had to give up his work as a printer. For some time before coming under my notice there had been very evident peristalsis from left to right in the epigastric region. Throughout the period over which his stomach symptoms extended his bowels had for the most part been very constipated but there were occasional attacks of diarrhœa. During this time he had attacks of what he described as "cramps" in his limbs and especially in his legs. He had lost very considerably in weight, as in December 1892 he weighed 9 stones 7½ pounds. On examination there was found well marked dilatation of the stomach, but the feature of the case which presented most interest in connexion with the present question was the occurrence while under observation of severe tetanic spasms affecting almost all the muscles of the body. So extreme and so widespread were these, the muscles of the trunk and of the cervical region as well as those of the limbs being affected, that on Jan. 17th the question of possible strychnine poisoning was raised. As palliative treatment of the stomach condition gave no relief the stomach was exposed on the 24th and the diagnosis of cicatricial stenosis with hypertrophy of the pylorus was confirmed. Pyloroplasty was performed, a bone bobbin being employed to insure patency of the new pylorus. Recovery was uninterrupted, and although the cramps were present up to the time of operation he never had a threatening of cramp afterwards. On Feb 15th he was able to take a mutton chop for his dinner without inconvenience and by March 2nd (five weeks after the operation) he had gained 8 pounds. Two years after the operation he had quite recovered his strength and was working as usual, his weight then being just over what it was in December, 1892, and quite 2 stones above what it was at the time of the operation. There had been no recurrence of "cramps" or of muscular spasms of any kind. In a letter received at the beginning of 1899 he speaks of some stomach disorder, but he adds "You will please understand that I am a new man to what I was when you saw me last." A recurrence of stenosis necessitated gastro enterostomy, which I performed early in 1902, but it is interesting to note that on this occasion, though he was much wasted and was vomiting every day, there was no return of the tetany. He made a good recovery and is now well and strong again.

17. Acute gastric dilatation is one of the most serious diseases that can be encountered. It was first described by the late Dr Fagge his paper being illustrated by two cases, both in men, 30 and 31 years of age respectively, and both ending fatally. In the Leeds Infirmary during the past ten years there have been at least four fatal cases. But that the condition of acute gastric dilatation is not hopeless the following case distinctly proves.

CASE 19.—A woman, aged 35 years, who was under my care, recovering smoothly from cholecystotomy which had been performed a week previously, was suddenly seized with pain in the epigastrium, followed by vomiting, which soon became ineffectual in emptying the stomach. Rapid dilatation ensued and the stomach not only formed a large swelling filling up the superior abdominal region but also extended well below the umbilicus towards the pubes. This, owing to pressure on the diaphragm, and through it to pressure on the heart and lungs, led to great shock, quick and oppressed breathing, and a rapid, feeble pulse, with signs of lividity and imperfect aeration of the blood. The urine was scanty and, in fact, was almost suppressed. Strychnine was freely administered subcutaneously, but no relief followed until the stomach tube was used when a large quantity of gas and several pints of brownish fluid were evacuated, the lavage was repeated several times during the next two days, during which time alimentation was entirely rectal. It is interesting to note that the pulse and temperature were paradoxical, the former running up to 150 and the latter down to 97 3° F. All the symptoms passed off under treatment almost as quickly as they came and in a week the stomach had returned to the normal size.

I would suggest that in every case of this kind where stomach lavage has failed, but only then (for the stomach tube is the first indication, no matter at what stage it may be recognised, unless, indeed, the patient be actually dying), the abdomen should be opened and the stomach should be emptied and connected with the jejunum, thus providing for continuous drainage into the intestine. I believe that as yet gastro-enterostomy for acute dilatation has not been put to the test.

18. In an exceptional case of ulcer of the stomach eroding the pancreas and producing pancreatitis with abscess draining into the stomach, a gastro-enterostomy apparently saved the life of the patient by draining the very foul contents directly into the intestine. The case is reported in "Diseases of the Stomach and their Surgical Treatment," p 168, so that I need not repeat the account here.

19. Cholelithiasis may lead to perigastritis and the contraction of bands of lymph around the pylorus may produce obstruction or kinking thus leading to dilatation of the stomach at the same time that the concretions lead to obstruction of the bile-ducts. As a rule the condition can be relieved by gastrolysis, but where the adhesions are extensive or the thickening of the pylorus is very pronounced the operation of gastro-enterostomy may have to be performed at the same time as the cholecystotomy. Gall stones may also lead to fistula between the gall bladder and pylorus and the thickening of the pyloric canal may lead to obstruction, for which gastro-enterostomy may be the most suitable operation, though in the cases that have come under my care the repair of the fistula in one case and pyloroplasty in another were sufficient when combined with cholecystotomy to remedy the disease.

20. In atonic dilatation of the stomach general and medical treatment, supplemented, if need be, by electrical treatment and lavage, if carried out systematically and for a sufficient length of time, usually yield good results, but in some cases, despite regular lavage of the dilated organ, well regulated diet, and general medical treatment, the dilatation persists and the nutrition of the patient and the general health become seriously impaired. In such cases

æmoptysis by the hypodermic injection of gelatin involves onstant and careful watching of the patient, such as can be atisfactorily carried out only in hospitals or similar nstitutions For the general practitioner it could be of o use.

This form of treatment has been applied with success in ther varieties of hæmorrhage. For instance, Holtschmidt[2] reated five cases of melæna neonatorum by hypodermic njections of a 2 per cent. solution of gelatin in normal saline olution, 15 cubic centimetres were injected, usually in two laces to avoid tension. The hæmorrhage was checked in ach case after the first or the second injection, and all ive patients recovered. Of the previous 14 cases in the ame clinic which were not treated by gelatin seven were atal.

On account of its many unpleasant complications the above reatment has not been used in Dr. Hettinger s sanatorium or a long time, the older methods being employed previously o the occurrence of the following case

The patient was admitted on March 3rd, 1902, having twice within the previous week brought up large quantities of blood. Hæmoptysis occurred again on the day of admission. On he next day bleeding occurred once more and the patient ost on each occasion about a quarter of a litre (nearly nine ounces) On the 6th there was another hæmoptysis. From this date until the 13th a more or less copious loss of blood occurred nearly every day Now that a fatal termination appeared imminent it was decided to employ gelatin, but in consequence of the strong objections to the hypodermic method the solution was given per rectum. On the 14th there was no hæmoptysis. The sputum was coloured. The rectal injection was repeated. During the next three days only traces of blood were seen in the sputum. The gelatin treatment was continued until the 17th when the sputum was free from colour. From this time forward the patient had no return of hæmoptysis

Encouraged by this success the treatment was applied in the same manner to four other patients during the months of April and May and was always attended by the same favourable result In one case in which the hæmoptysis was of comparatively slight degree two injections a day were sufficient to free the sputum from any trace of blood, but it was the rule to give three injections per diem. In all the other cases the sputum was clear of blood within four or five days of the first injection Since May 15 more cases have been treated at the sanatorium in a like manner, and in each case with unqualified success Slight cases in which a small quantity of blood was brought up on only one occasion did not receive this treatment. Others who have tried this method report equally good results

In contradistinction to the hypodermic injection the method here described is quite painless. Further, every danger of infection is avoided Also no raising of the temperature is produced and of course, there is no necrosis. In short, the rectal injection of gelatin solution is unattended by any disturbing complication and it has the same effect in stopping hæmorrhage as has the subcutaneous injection. A strong point in favour of this method is that it can easily be carried out in general practice. The gelatin can be obtained from a druggist or from a restaurant and the only apparatus necessary is a jug holding about two and a half pints and an indiarubber tube with a blunt nozzle The nozzle can be held in the rectum by the patient himself while the nurse holds the vessel containing the solution at a height of about two or three feet so that the solution flows into the rectum at a very moderate pressure When the hæmorrhage has been completely stopped the patient must be kept quiet in bed for several days on a light diet. It may here be mentioned that the injection does not cause any action of the bowels.

The solution is prepared in the following manner 50 grammes (about one and three quarter ounces) of gelatin are dissolved in one and a quarter litres (two pints three and three-quarter ounces) of boiling water and boiled very gently for one hour when the volume is reduced by evaporation to one litre The solution is then cooled down to the body temperature and a quarter of a litre (nearly nine ounces) is slowly passed into the rectum from an ordinary irrigator in the manner described above. The injection is given three times a day until the sputum ceases to show any trace of blood.

Nordrach Schwarzwald.

THE USES OF X RAYS IN OPHTHALMIC SURGERY[1]

BY M. S MAYOU, F.R.C.S. ENG.,
CHIEF CLINICAL ASSISTANT TO THE ROYAL EYE HOSPITAL, SOUTHWARK.

I HAVE to thank you for the honour you have conferred on me in asking me to read a paper before this society to-night I accepted, as I hope that I may be able to show in some small degree how this comparatively new science may be far reaching in its extent, even in this one branch of medical science—ophthalmic surgery My experience has extended over the last 18 months, during which time I have daily undertaken the treatment and investigation of cases, and I have to thank Mr L. V Cargill, Dr F H. Low, Dr O F Grünbaum, and others for their kindness in sending me cases and for their opinion on these cases during and after the treatment. The whole question is too large to deal with to-night and I propose to select the following subjects from it (1) the localisation and treatment of metallic foreign bodies in the globe, (2) rodent ulcer of the eyelids—the pathology of the cure, and (3) the treatment of trachoma—granular ophthalmia.

1 *Foreign bodies in the globe*—It is not out of place to repeat how invaluable these methods of radiography and localisation are to ophthalmic surgery and the great boon that Mackenzie Davidson has conferred on us During the last year I have had sent to me from the Royal Eye Hospital, the Seamen's Hospital, and King's College Hospital 16 cases of supposed foreign bodies in the globe, of these, 13 were found and localised, two eyes contained no foreign body, and one was missed about which I wish to speak later Of the 13 all were verified and found to be accurate. The method adopted was as follows In recent cases and cases where there was much photophobia a wire stitch was fixed in the conjunctiva directly below the centre of the corneal margin, the eye having been first cocainised, but in cases where there was no photophobia a piece of fine wire was fixed over the lower lid and kept in position by the lashes and the patient was directed to gaze at some object so as to bring the corneal margin in contact with the summit of the loop.

The head was fixed in a Mackenzie-Davidson head rest, taking care that the cross wire did not fall across the orbit I wish to emphasise this point, as it was due to this occurring that the case mentioned above was missed, the shadow of the foreign body, which measured barely a millimetre, falling across the shadow of the wire and being obscured by it It was subsequently extracted in the lens, which had become opaque, so no harm followed. Two separate photographs are taken, as they are liable to render the images indistinct when taken on the same plate This is done twice over as I have seen a foreign body missed in two successive photographs owing to the patient moving his eye and making the image of the foreign body which was a very small one, indistinct. Half a minute s exposure is generally sufficient The method of subsequent localisation is worked out on a drawing board, it is cheap, efficient, and takes practically no more time than other methods. Having found the relation of the foreign body to the cross wire and to the wire on the lid, the next thing to do is to mark it on an eye drawn to scale, such as can be found in Quain s *Anatomy* and observe its relation to the various structures of the globe. The shape of the foreign body is determined by using some form of stereoscope and the one I find most convenient is a modification of Wheatstone's which I have had made to take negatives, it can be used at once after developing the negative as immediate extraction of the foreign body is of the utmost importance.

The size of the foreign body should be very carefully measured, as the size of the incision for its removal must be regulated by it. I cannot emphasise too much the importance of immediate localisation and removal of foreign bodies as (1) they are said to be the most fertile source of sympathetic ophthalmia, (2) they are more likely to give rise to suppuration if left, and (3) if left for a day or two they become rapidly encapsuled and often defy extraction with the electro-magnet. In two of the cases I have mentioned, the minds of well-meaning but ill-informed philanthropists and to bring into bold relief the danger of giving a free hand to those impecunious persons who bombard us with applications for the care of this class of patient. One of these individuals who was anxious to obtain the care of such a one endeavoured to impress upon me that blindness and being crippled would not matter. I presume if the unfortunate patient was blind he could not see and criticise his food and surroundings, and if crippled he could not escape and would require less expensive supervision.

---

[2] Münchener Medicinische Wochenschrift Jan. 7th.

[1] A paper read before the Roentgen Society on Dec. 4th 1902.

It has been suggested that the relatives of many certified patients should take them out of asylums because they are not dangerous to themselves and others and that they could undertake the care of such cases as well as, or even better than, they could be cared for in an asylum without the "stigma" attaching to them of being certified lunatics. This to my mind is mere sentiment; nothing can alter the fact that the patients are insane whether they are certified or notified and, whether the fastidious friends like it or not, the fact remains. My experience through a long series of years spent among the insane is that more downright cruelty and neglect are often inflicted upon such patients by friends and relatives owing to their ignorance and incompetence, and through judgment giving way to feeling than are possible under the splendidly humane treatment of such cases in our institutions for the insane, private as well as public, which are a credit and an honour to our country.

In support of this statement permit me to give you an account of a case which came under my notice a short time ago. [Dr. Wood here gave details of the case and continued.]

I confess to being somewhat shocked at such a condition of things occurring in the closing months of 1902. But these are the evasions of the law which we must expect to increase and to multiply if the law is made "more elastic" with regard to cases of certifiable insanity without adequate official supervision. I do not wish to weary you with a recapitulation of further instances of the inhumanity of ignorance which are only too well known to us, but I venture to say that if the supervision of the certifiable insane in single care by the Commissioners in Lunacy is in any way relaxed we shall soon have a recrudescence of those scandals which brought on to the statute-book the Lunacy Law as it now stands. No perfunctory visitations of the physician can prevent them. Only within the last month I had three applicants for the post of nurse to a mental case and in view of the question which I have raised of asylum trained nurses being so necessary for the care of mental cases permit me to describe to you the kind of persons these three applicants were. [Here Dr. Wood gave details of his interviews with would-be mental nurses.] Then there is a further view of the subject which the following incident illustrates and it is a pretty example of another method of evading the law. [Details were here given.] We have arrived at a serious state of thing if consultants, either unable or unwilling to recognise a case of acute mania, can bring themselves to call it "hysteria" in order that they may pander to the pride and prejudice of fastidious relatives who look upon this one of the most affecting disorders that can afflict a fellow creature, as a crime or something to be ashamed of. Is it not rather the duty of a consultant to support the medical practitioner in his endeavour to induce the relatives of the sufferer to take a sane view of her malady and to do their best for her rather than to hand her over to such untrained and unreliable people as I have described to be "policemaned" as a case of "hysteria"?

They who have spent their lives in endeavouring to ameliorate the condition of the insane must not stand by without protest and allow a reversion to those methods of barbarism which would be bound to follow any relaxation of the law without something more to protect the unfortunate patients than the mere visits of a physician who may have no special knowledge of the care and treatment which they require. Above all, we must be satisfied that those who are allowed to take charge of insane patients are properly trained and competent to do justice to their charge.

The point upon which the whole question hangs is that of adequate supervision. It is a very simple one. The Commissioners in Lunacy have all the facts in their possession. There is no need for any commission of inquiry about Laws. We know quite enough about them with local expert representatives of the Lunacy Board in centres of the population will, in my opinion, meet every requirement. By these means the vagaries of those who take charge of cases of doubtful or confirmed insanity will be held in check, and the friends and relatives will be controlled and guided by the firm but kindly supervision of trained experts who are qualified by long experience to guide and to direct them in the right way.

Margaret-street, W.

THE
GELATIN TREATMENT OF HÆMOPTYSIS.

BY H. M. TICKELL, M.A., M.D., B.C. CANTAB.

IT must be admitted that the usual methods of treating hæmoptysis have not by any means attained that degree of efficiency which this distressing and dangerous complication of pulmonary tuberculosis demands, and that an agent capable of acting with greater certainty than those in common use will be cordially welcomed by the medical profession. Of the old drugs, morphia is the most highly recommended, and doubtless, when injected hypodermically, it exercises a favourable influence by relieving mental distress, allaying cough, and quieting the action of the heart, and by these means promoting coagulation in the smaller vessels. But, on the other hand, there are some cases in which morphia increases the tendency to asphyxia by retarding the expulsion of blood from the bronchi and this is a danger always to be borne in mind. The treatment by morphia, moreover, gives no security for the final arrest of the hæmorrhage, and in the severer degrees of hæmoptysis it fails us entirely.

In the treatment by means of the rectal injection of the solution of gelatin presently to be described we have a method of checking hæmoptysis which promises exceedingly well, and one which is free from the drawbacks of morphia. In the *Aerztliche Mittheilungen* of Sept. 17th, 1902, appeared an article on the Gelatin Treatment of Hæmoptysis by Dr. Jungmann, assistant to Dr. Hettinger of Nordrach, and I am indebted to the author for much valuable information on the subject.

First, let us consider the treatment by hypodermic injections of the gelatin solution. This method has been used in France and Germany with brilliant results as regards the checking of hæmorrhage, but unfortunately it is associated with a series of unpleasant effects which at times are of such a nature as seriously to call in question the utility of the proceeding. In the first place the injection is accompanied with severe pain which is due not so much to the puncture of the skin as to the distension of the tissues by the solution. Even if a local anæsthetic be employed the pains usually supervene shortly after the operation and may persist for two or three hours, and when the operation has to be repeated several times on successive days the painfulness of the procedure becomes a matter of serious consideration. Again, not infrequently necrosis of the skin occurs as a consequence of the injection, so that the patient has to remain a long time in bed—a most unfortunate circumstance from the point of view of open-air treatment. In some cases tetanus has been observed to ensue. Levy and Bruns[1] examined six samples of gelatin and found tetanus spores in four of them. It is, therefore, necessary to sterilise the gelatin before use. The question as to whether prolonged boiling destroys the value of gelatin as a hæmostatic may, according to experience in Dr. Hettinger's sanatorium, be answered in the negative.

The most disagreeable effect of the hypodermic injection of gelatin undoubtedly consists in the raising of the body temperature. As reported from Brehmer's Institute in Gorbersdorf, one patient treated with the gelatin injections on five successive evenings had a temperature of from 40.3° to 40.7° C. (104.5° to 105.2° F.). The subsidence of the fever is irregular, but it may persist for 10 or 14 days and thus increase the debilitation of the patient.

All these observations show that the treatment of disease, if such organism be present. Taking the first of these, the method we adopt very commonly is the application of copper sulphate or some mild caustic. At each application we destroy the epithelium of the conjunctiva on which we rub it, and although we cure the trachoma an excessive amount of scar tissue is left, causing entropion and other deformities of the lid. As regards rolling brushing, and other operations, they have the additional advantage of removing the actual diseased tissue, but it is generally recognised that they are only suitable for certain cases and that even in these cases the cure is not generally complete unless they are followed by some form of caustic to keep up the irritation set up by the operation.

---

[1] Deutsche Medicinische Wochenschrift, Feb. 20th, 1902.

In the x rays we have a method of setting up a leucocytosis with the absolute minimum of destruction to epithelial and other tissues, and further we have a means of producing an inflammation from a very slight leucocytosis to an actual gangrene of the part which with due care and experience we have under almost perfect control. Not knowing the organism which causes trachoma we cannot say whether the irritants which are used in its treatment, or the x rays, have any effect on it. But we have in the x rays a method of producing leucocytosis in any degree of severity from that following a mild application of perchloride of mercury up to that induced by jequirity, and, further, this leucocytosis is much more prolonged than that in any method previously adopted and the destruction is not nearly so great. Although granules disappear very rapidly under the x rays operative methods, which have the additional advantage of removing the diseased tissue, must be preferable to some extent except that the patient has to undergo an operation, but such operations can be followed by the x rays to complete the work in preference to one of the other irritants now in use. Operation, however, should never follow x ray treatment without a considerable interval.

At the beginning of 1902 I showed before the Ophthalmological Society a case of trachoma which had been treated by the x rays and which, so far as I know, was the first of its kind. The method adopted was to cover the whole face, with the exception of the affected eye, with a metal mask. (Since then I have discarded the mask altogether, as now I never expose the patient sufficiently to get any reaction at all in the skin.) The upper lid was then everted and the lower lid was pushed up so as to cover as much of the cornea as possible, but in bad cases of pannus the cornea is left exposed. I have never had any trouble with the globe following x ray treatment, and in a case of rodent ulcer of the lid in which this treatment was used for six months and which I showed at the same society last June there were no signs of retinal, corneal, or other trouble, with the exception of conjunctivitis, and the patient's vision remained the same ([illegible]) throughout the treatment. The patient is seated about nine inches from the anode with a moderately soft tube and a current of six ampères Two minutes exposure is given for from four to six successive days, depending on the case. If there be much injection or the case be an acute one four are generally sufficient. A week's rest is then given and if no reaction is set up the patient is exposed twice a week until there is a slight increase in the photophobia, which shows that he is beginning to react. About this time the granules begin to disappear from the lids. Exposures once, twice, or three times a week are carried out until they disappear entirely When once the granules have disappeared all treatment must be stopped, as it requires some weeks for the infiltration set up by the x rays to settle down and it is difficult to tell whether the disease is absolutely eradicated as the lid remains injected for some time after treatment has ceased The final result to the lid is most satisfactory Instead of the white puckered conjunctiva gained by other methods a supple, non contracted, non scarred conjunctiva, with no obliteration of the fornices unless they are already gone before treatment, is produced, similar to the soft, supple scar in the skin following this form of treatment in rodent ulcer, as compared with the dense cicatrix of excision.

As regards the effect on pannus, it often clears with great rapidity, especially if recent, and it is the common thing for patients to say that they see more clearly from almost the first exposure. But even dense corneal opacity will often clear considerably and in one case of extensive destruction and cicatrisation of the cornea, in which at the commencement of treatment the patient could only see shadows, in two months she could count fingers three feet away Another peculiar point is the amount of exposure required by different patients. Sometimes the granules begin to disappear from almost the first exposure, others require eight or ten exposures before showing signs of reaction.

With regard to the cases suitable for treatment the most satisfactory are the chronic cases, and of course the earlier they seek treatment the more rapid and satisfactory is the result. These patients will stand more frequent exposure than any others, acute diffuse infiltrations with thickening of the lids and much photophobia require more careful exposures extending over a much longer period. Old-standing cases in which the lid trouble has almost disappeared, but in which there is much opacity of the cornea, will often improve considerably under exposures of long intervals after the first reaction, which should be mild. The chief advantages of this treatment are (1) there is considerably less deformity in the lid after treatment, (2) it is practically painless treatment, and (3) pannus clears more thoroughly It is eminently suitable for hospital patients who cannot attend daily for the other methods of treatment to be carried out In the first cases the patients were troubled with some falling out of the lashes and conjunctivitis *In no other case out of some 15 has there been similar trouble.*

Weymouth-street W

THE TREATMENT OF EPILEPTICS

BY FLETCHER BEACH, M.B F R.C.P LOND,

PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES EPILEPSY AND PARALYSIS PHYSICIAN TO THE CHALFONT COLONY FOR EPILEPTICS

As I had no opportunity, owing to want of time, to join in the discussion on Dr J S Risien Russell's and Sir Victor Horsley's admirable papers on the Treatment of Epileptics which were read before the Medical Society of London on Feb 9th,[1] I take the occasion to make some observations on the subject in the columns of THE LANCET

Among the causes of epilepsy described by Dr Russell and Sir Victor Horsley no mention was made of errors of refraction, which my colleague Mr Work Dodd in a paper in the sixteenth volume of *Brain*, showed might be a cause of epilepsy He examined 100 consecutive cases of this affection and found that by correcting the errors of refraction, in combination with other treatment, 49 were cured or relieved. I think that this is a point which is worthy of attention by the medical profession. I am in agreement with Dr Russell and Dr C E. Beevor that a toxic cause of epilepsy has not yet been proved, though I admit that when bromism has been produced great benefit will be derived by the use of hot baths, internal antiseptics, and saline enemas. In most cases there is neurotic inheritance and an exciting cause is only necessary to produce a fit. This is an indication that all exciting causes, such as indigestion, constipation, the use of alcohol, irregular meals, late hours, the presence of worms, &c, should be removed as much as possible I am in favour of limiting the amount of meat to be consumed by the patient, and in some cases of omitting it altogether, certainly at the commencement of the treatment, for I have noticed in cases in which much meat is eaten that there is great difficulty in reducing the number of fits I believe that what may be called the home treatment of epilepsy is of importance. The patient should lead a quiet life, free from excitement, and should be subjected to cold baths or cold sponging daily Outdoor exercise and a moderate degree of mental work are necessary and care should be taken to place the patient in such circumstances as will promote his welfare and recovery It is necessary that he should be careful, prudent, and temperate in all things. Children who are the offspring of a neurotic family require to be brought up carefully, and later should be put into some occupation in which they will be free from excitement and worry, such as the Civil Service, in which the work is light and the hours of employment are not long

With reference to the treatment by drugs, I am in favour of giving large doses of the bromide and I prefer the combination of ammonium, sodium, and potassium. If for any although the magnet was literally applied to the foreign body which was in the lens, it could not be withdrawn, and out of seven recent cases in which the foreign body was in the vitreous and had penetrated the lens only one eye was saved, this foreign body had been in the eye only four hours In cases in which foreign bodies have been in the eye some time, although they are generally small and aseptic, the prognosis as regards extraction is not good, as they become encapsuled, which may lead subsequently to siderosis, &c., unless situated in the lens, when they can be extracted with that body with good result

---

[1] THE LANCET Feb 14th, 1903, p. 439

In operating for these foreign bodies the best method, except in a few cases when the foreign body is in the lens, is to use a small electro magnet. I must say here that I have not seen the large magnet used very much, but it always seems to me that the traction of a foreign body through the globe regardless of structures is a most unscientific procedure, causing vast injury to the intra ocular contents. I have seen more than one case in my limited experience in which the eye would have been destroyed if this method had been adopted, and although I have read Mr A. F MacCallan's valuable paper on the subject I still think that the Haab's magnet should only be used after failure of the small one The incision in the globe must be large enough to admit the magnet and to allow the foreign body to come out, and the magnet is applied, if possible, to the narrowest diameter of the foreign body When the foreign body is lying in the vitreous I think equatorial incisions are preferable to radial, as they are more easily held apart and do not go so near the ciliary body No stitches are necessary in the sclera and it is better if possible to cover the wound with conjunctiva and muscle by turning them back in a flap before incising the globe and having the sutures in readiness for immediate closure of the wound, after the method which, I believe, was first introduced by Mr Cargill

Going once more over the salient points as regards the method of localisation (1) immediate localisation to be repeated if the foreign body be not found, (2) the use of separate plates, (3) care to be taken not to let the cross wires fall within the shadow of the orbit, (4) localisation and estimation of size, and (5) the use of the stereoscope for the estimation of the shape, preferably one made for negatives, as it saves time

The points to be determined by the x rays before operating are (1) the size and shape of the foreign body, (2) the situation with regard to the intra ocular contents, and (3) the position of the foreign body with regard to the wound to be made in the globe for its extraction or with regard to the entrance wound.

Prognosis is influenced, apart from points defined by the x rays, by the following considerations (1) the nature of the case—i e, recent or old standing, (2) the condition and size of the foreign body on entrance, (3) the situation and size of the entrance wound, and (4) injury to the intra ocular contents

2 *Rodent ulcer of the eyelids* —The eyelids are a common site for rodent ulcer, especially the lower, and, like rodent ulcers in other situations, can be cured by the application of the x rays. I do not propose to night to speak much of the methods of exposure, but of the pathology of the cure and some of the changes found in the tissues. When the x rays are applied to healthy living tissues the most noticeable effect is an acute inflammation in the part, which does not extend deeply into the tissues but is quite superficial. The peculiarity of this inflammation is that it does not reach its full height until some time after the exposure, say in from one to three weeks. This inflammation is greatly increased and more rapidly brought about by simultaneously applying irritants. This point I want to emphasise and to illustrate by one or two cases, as I think it is not generally noted. A man was sent to me to be x rayed for a superficial epithelioma of the hand. After about two weeks' exposure it was thought to be increasing in size, so a local excision of the growth was performed. So much sloughing occurred that the arm had to be amputated above the elbow Some time ago I had rather a severe x ray burn on my hand and I found that the least irritation, such as washing my hand, caused it to become hot, painful, and bright red, and after assisting at an operation and putting my hands in 1 in 20 carbolic acid solution extensive sloughing of the skin followed This observation led me to use 1 in 20 carbolic acid solution for dressing rodent ulcers in the early stages of x ray treatment whenever possible, and this I find has the double advantage of keeping them aseptic and of accelerating primary reaction

This susceptibility to irritants can be largely accounted for by the vaso-motor paralysis which occurs in an inflamed part and which when more irritation is applied, leads to greater dilatation of the vessels. This dilatation of the vessels seems to be permanent at the seat of the most acute inflammation, for if a part be examined after recovery from an x ray burn dilated vessels can be seen all over the area. This increased susceptibility to irritants is a most important factor in the healing of rodent ulcer, for I think it is largely due to the irritation produced by the rodent cells on the surrounding tissues that the x rays have such a wonderful effect. Otherwise, why should the new growth disintegrate and not the surrounding tissue?

By the application of the x rays to a part we can produce an inflammation leading to anything from a mild leucocytosis to an actual gangrene. This is brought about I think in exactly the same way as an inflammation is produced by other forms of stimuli and is most severe at the point first struck—i.e, the superficial tissues. All evidence tends to show that this form of energy does not penetrate deeply and is probably not produced by the rays which penetrate the body

In rodent ulcer the tissues are invaded by a new growth which sets up a slight inflammation, and this in all probability is nature's method of trying to rid herself of the disease At the same time the growth is dependent on the underlying tissues for its nutrition Now if we excite an acute inflammation the part furthest from the sources of nutrition dies and will come away as a slough This will therefore account for the disappearance of the large masses of nodular growth which so rapidly subside under treatment. But if a section of rodent ulcer be examined we find lying under apparently healthy skin cells of the growth. Now how is it that these cells disappear also, as they obviously cannot be thrown off as sloughs? If a section of rodent ulcer after it has just begun to react to the x rays be examined we find that the clumps of epithelial cells which make up the growth are surrounded with enormous numbers of leucocytes It is the duty of these leucocytes to remove all irritating substances from the part by breaking them up and carrying them away, or, failing that, to encapsule them with fibrous tissue, shut off their nutrition, and so prevent their spread. In a section of rodent ulcer which has nearly healed we find a mass of granulation tissue organising, with healthy epithelium growing in from the edge, scattered here and there amongst the infiltration leucocytes are epithelial cells of the growth in various stages of degeneration The degeneration seems to take place from without inwards towards the centre of the clumps of epithelial cells, which become vacuolated, and the granules in the cells multiply and collect around the cell wall, seem in places to be making their way through it, and finally disappear The nuclei do not as a rule proliferate although there are some large cells with multiple nuclei to be seen which are probably derived from the stroma. The chromatin ceases gradually to take up the stain until nothing but the cell wall remains which is apparently removed by the leucocytes In treating a rodent ulcer I find it most useful to remove portions of the growth from time to time to see if there are any active cells of the growth present and if they have all disappeared to cease treatment.

3. *The treatment of trachoma by the x rays* —In treating any disease it is almost essential that we should first know its exact pathology Although a great deal of work has been done in the pathology of trachoma we are not yet absolutely sure that the exact causative factor has been discovered and therefore cannot be sure that any treatment adopted is the best possible In trachoma we have a disease which is very closely allied to lupus in many respects in that it is characterised by the formation of nodules or infiltrations consisting of masses of round cells, and there is every evidence that the disease is probably due to some organism closely allied to the tubercle bacillus.

At the present time trachoma is cured by applying some form of irritant to the lid, either by chemical means, such as copper sulphate, corrosive sublimate, or jequirity, or mechanically by rolling, brushing, or other operative methods. These irritants must act in one of two ways either (1) simply by the reaction they set up, partly by causing a leucocytosis and subsequent cicatrisation of the nodules, and partly by mechanically removing the diseased tissues, or (2) by direct action on the organism causing the

FIG 1

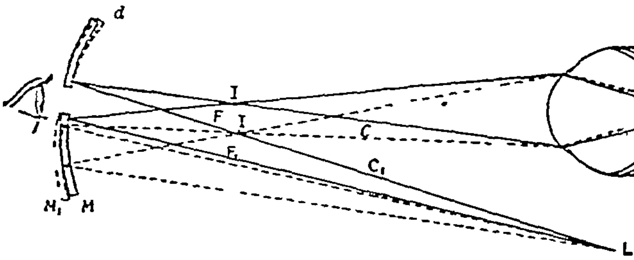

FIG. 2.

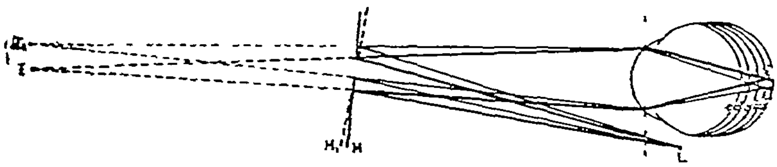

FIG. 3

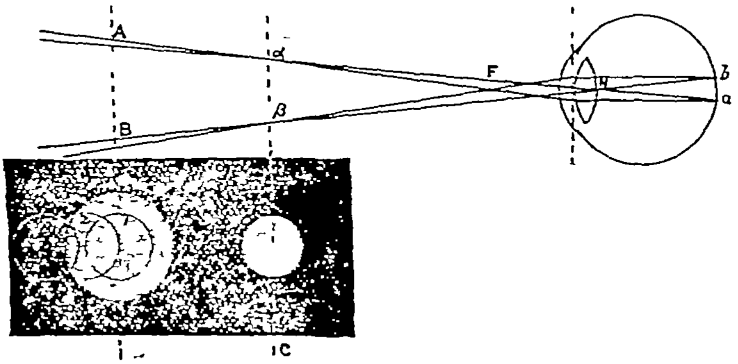

FIG. 4

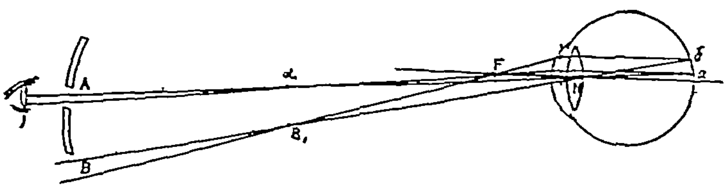

FIG 5.

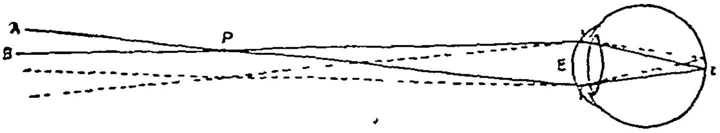

FIG 6

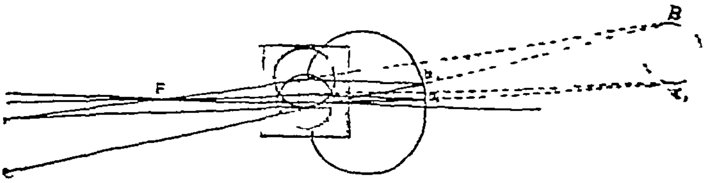

P, coincides with the focus of the mirror. On account of this coincidence there is formed on the retina of the observed eye an exact and well defined image, *i*, of F (which in its turn is an image of L, Fig 1) Hence the rays emerge from the image in the eye along the same path as they entered, P and *i* being conjugate foci

The shape of the emergent beam is shown in Fig 5, and it is seen that the cone is very narrow in section and may even all be included in the sight-hole of the mirror The illumination is a maximum and a *very slight* movement of the mirror is enough to send the cone right off the sight-hole, as shown by the dotted lines, and so the edge of the shadow is difficult to observe (be it noted that a reflected ray moves at *twice* the angular rate of the mirror)

Now since we have assumed the distance P E to be one metre, it is obvious that a − 1 D lens, placed in front of the eye would remove the far-point to infinity—in other words, render the rays parallel. Hence this is a case of myopia 1 D, and it may be regarded as the limiting case between movement *with* and movement *against*.

(*b*) 2. *Myopia of less than* 1 D, in which the remote point lies further away than P, is not often met with in practice, as so little inconvenience is experienced that it is hardly worth correcting being actually a real convenience for close work like reading &c, and cannot be accurately gauged by the method of retinoscopy, as the movements of the shadow are difficult to observe, for the same reasons as before. Such cases must be settled at the test-types

(*c*) *Emmetropia.*—In this case the diffusion-circle of illumination is very small (see Fig 1) and is situated at the principal focus of the eye, so that the emergent beam consists of bundles of parallel rays coming from points of light in the circle. The section of this beam is nearly the same at every point and is of about the size of the patient's pupil The illumination, as seen by the observer, is bright, but the shadow movement, which is "against," is not easy to detect for reasons already given.

(*d*) *Low hypermetropia*—Rays from any point of light in the circle of illumination continue to be divergent after passing out of the eye and so never cross as in case *a* (myopia), but their directions, if produced backwards, do meet and form a virtual image of the point behind the eye This is shown in Fig 6 and is the reason why the shadow moves against instead of with.

$\alpha\ \beta$ is a virtual image of $a\ b$ As in all the other cases when the mirror is tilted down $a\ b$ goes up and, therefore, also $\alpha\ \beta$. In Fig 6, $a_1\ b_1$ is the new position of $a\ b$ and $\alpha_1\ \beta_1$ of $\alpha\ \beta$. This is movement against. The appearance seen is represented by the shaded projection, where the lower circle represents the pupil, and the upper the virtual image $\alpha_1\ \beta_1$

(*e*) *High hypermetropia.*—In this case the diffusion-circle of illumination is larger and the emergent rays are more divergent than in *d* Hence, also the virtual image $\alpha\ \beta$ is larger and, therefore, not so bright and being larger the shadow is more crescentic.

Wimpole-street, W

reason this combination is not desirable and only one salt is required, I give the bromide of ammonium as it is not so depressing as the bromide of potassium In this statement I think I am in agreement with Dr Beevor In some cases I have found a combination of antipyrin with the bromide useful. The use of this drug for this purpose was brought to my notice by my colleague, Dr A. de Watteville, some time ago and I prescribe it in doses of five grains three times daily for children and ten grains three times daily for adults. I have noticed that in many cases where the bromide alone has not produced much result so far as the lessening of the fits is concerned the addition of antipyrin has proved useful, and this result is no doubt due to its analgesic properties. In cases where the fits occur at night only I direct the patient to take just before going to bed or to be given a double dose of the bromide if the fits be infrequent and to take a large dose only at night if a great number of fits occur It will often be useful to give a large dose of the bromide at night in the cases of clerks and workmen who are apt to forget to take the medicine during the day, whereas if it is given at night this forgetfulness is not so likely to occur If the fits come on in the early morning a large dose should be given before the patient gets up and he should remain in bed for at least an hour after the dose is taken if possible. With regard to the reduction of chlorides in the diet to make the patient more sensitive to the use of bromides, although a less quantity of the bromide is necessary for daily administration, it appears to me that this plan has not sufficient evidence in its favour to warrant its use in the treatment of epilepsy, and in any case it cannot be continued for a long time in consequence of its interference with nutrition. As to the length of time during which the bromide should be administered, I am in favour of giving it for two years after the last fit in ordinary cases, and for three years in a few cases where circumstances render it necessary During the time that the bromide is being taken by the patient it will be well to give iron tonics and cod liver oil to maintain the nutrition. The bowels should be kept well open and occasionally high rectal saline douches should be given

As to the treatment in colonies, which was only briefly touched upon experience has shown that the result is most gratifying In many cases the colonist has lived in a town and removal to the country has a good effect, because it is known that life in the open air is very necessary for epileptics. The general health is improved, the fits are diminished, and the colonists help to furnish a variety of food which is desirable in the treatment of the affection Employment is particularly necessary, not only because it gives the colonist no time to brood over his malady, but because farm and garden pursuits bring him into the sunshine, fresh air, and other surroundings which inspire him with mental activity and hopefulness. As far as the colonial treatment of children is concerned, wherever it has been tried it has been followed with good results A recent Act of Parliament, the Elementary Education (Defective and Epileptic Children) Act, has so far interfered with the treatment of epileptic children in colonies in England, but it is hoped that this Act will soon be modified and permit epileptic children to benefit by the treatment which is so necessary for them

In the above remarks I have not attempted to give a full account of the treatment of epilepsy but only to make some observations which have occurred to me and which I could not state at the meeting after the papers of Dr Russell and Sir Victor Horsley were read.

Wimpole-street W

ROYAL INSTITUTION — The Friday evening discourse at the Royal Institution on Feb 20th was delivered by Principal E. H. Griffiths of the University College of South Wales and Monmouthshire. The subject of the discourse was the Measurement of Energy with special reference to the mechanical equivalent of heat. Joule's original determination was that 772 foot-pounds of work were equivalent to the heat required for raising the temperature of a pound of water by 1° F Referred to the centigrade thermometer and to the units of the metric system this expression becomes $4\ 156 \times 10^7$ ergs per gramme-degree. Later experiments have shown that this estimate is somewhat too low and that the number of ergs per gramme-degree centigrade is more correctly stated as $10^7 \times 4\ 185$ or 4 186. Professor H L. Callendar's apparatus for performing the experiment was exhibited in action.

THE THEORY OF RETINOSCOPY

BY E KENNETH CAMPBELL, M B. EDIN , F R.C S ENG ,
SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL, LONDON

As the theory of retinoscopy is very inadequately dealt with in the text-books the following, which is a complete account of its optical principles as worked out on Frost's artificial eye, may prove interesting to readers of THE LANCET

Let L be the source of light and M a concave mirror, with its centre of curvature at C, and focus at F about 20 centimetres from M. There will be an image of L formed at I, a little above and to the right of F (see Fig 1). Let i represent the image formed on the retina b, then it follows that retinæ in other positions, as a, c, d, e, will have diffusion circles of light formed upon them.

If I be the far point of the eye, then it is one of low myopia, I being distant about one metre, and the position of the retina will be that of b In the other cases represented—a, high myopia, c, emmetropia, d, low hypermetropia, and e, high hypermetropia—diffusion circles are formed proportional in size to the amount of ametropia.

When the mirror is tilted downwards (into the dotted position M_1), I goes to I_1, and i goes to i_1—i.e., against the mirror Also, all the aforesaid diffusion circles go the same way—*against*.

If M be the position of the mirror (plane), then an image (virtual) of L is formed at I (as far behind M as L is in front) and an image (real) of I is formed at i on the retina b, diffusion circles being formed on retinæ in other positions, as a, c, d, e (see Fig 2) When the mirror is rotated downwards to the position M_1, then I goes to I_1 and i goes to i_1—i.e , downwards—and the diffusion circles go the same way This is just the opposite of what takes place with a concave mirror (see Fig 1) b is the retina of a low myopic eye, the far point of which is at I

Now, having seen how the retina in the observed eye receives its illumination and that this always moves *against* the concave mirror, let us omit from subsequent diagrams all the rays concerned in the formation of this illuminated area and consider only those which leave the retina, pass through the lens, and enter the eye of the observer, and we shall take the five cases mentioned and consider each separately

(*a*) *High myopia* —Here we have a diffusion circle, $a\ b$, upon the retina, because it is further back than the focal plane of the refracting media of the eye, the rays having crossed at i (Fig 1) and an image of this circle is formed in the air at $\alpha\ \beta$, as shown in Fig 3 the construction being to draw a ray through the nodal point undeviated and another parallel to the axis, and refracted at the principal plane through the anterior focal point F Such rays cross at $\alpha\ \beta$ and here is formed a real aerial image of $a\ b$ Since the observer is accommodated for the pupil and not for the image its edge appears ill-defined, as shown in the figure

Suppose now, by a downward tilt of the mirror, $a\ b$ is made to go to $a_1\ b_1$ (Fig 4) then the emergent cone of rays, A F B and the image $\alpha_1\ \beta_1$, go downwards—i e., sweep across the front of the mirror—and presently the more or less ill defined edge of the cone sweeps across the sight-hole and, when it is just passing, the eye behind the hole sees the light disappear downwards, followed by the concave edge of the shadow, and the field of vision—i.e , the observed pupil—at different stages of the sweep is represented by the circles 1, 2, and 3 in Fig 3 Owing to the largeness of the diffusion circle, $a\ b$, the illumination is seen to be somewhat feeble and the shadow is not very wide.

(*b*) *Low myopia.*—Here the cone of rays is not so divergent, for as we approach emmetropia they become more and more nearly parallel, the section of the cone is smaller, the illumination is brighter, and the edge of it is more curved than before and the width of the shadow is greater

(*b*) 1. *Particular case of low myopia* in which the far point, behind the sternum, accompanied by a slight cough but by no pain. This soon passed off, its occurrence being completely forgotten. Early in the following January he had a somewhat severe attack of "influenza," followed shortly afterwards by a relapse both attacks being accompanied by severe coughing and a slight amount of expectoration of thick yellowish muco-purulent material. During the relapse he suddenly developed aphonia for several days, preceded by slight huskiness of the voice, but unaccompanied by any pain. The cough and slight muco-purulent expectoration, however, continued and in March, 1902, he had an attack of dry pleurisy over the outer aspect of the left lower lobe. On recovering from this he went to the country in the hope of hastening convalescence, but while there he was much troubled by severe attacks of coughing The cough was dry and hard and expectoration was very scanty, but later it became somewhat more abundant It was especially troublesome at night, often awakening the patient from sleep and was accompanied by a feeling of irritation behind the upper part of the sternum. He also noticed that these attacks of coughing were brought on by the act of stooping, and on these occasions he sometimes brought up a considerable quantity of thin whitish sputum. In July and August he went for a six weeks sea voyage and improved considerably in general health, the cough and thick muco-purulent expectoration, however, continuing unabated. These symptoms remained unchanged until Friday, Jan. 30th, 1903, when he had a sudden hæmoptysis while walking along the street, preceded by some coughing He remained in bed during Saturday and Sunday and on Monday morning he again went out, but owing to a recurrence of the hæmoptysis had to return home. Shortly afterwards, while lying quietly in bed, he felt a "sort of obstruction" in the chest and coughed up a large mouthful of bright red clotted blood. In this he felt something hard which on examination proved to be the fang of an upper molar tooth with a large cavity at its upper end, the edges of which were so sharp and ragged that it must have caused considerable damage to the tissues in which it had lain imbedded for over a year I saw the patient last October for my father, Dr George Dickson, Edinburgh, and neither of us for a moment suspected that the case was other than one of early phthisis, the patient at that time dating the commencement of his illness from the attacks of influenza in January, 1902, and having entirely forgotten the occurrence of the slight cough and expectoration after the extraction of his teeth in the preceding December He was also seen by a consulting physician in Edinburgh who had his sputum examined for tubercle bacillus with negative results. The case is one of considerable interest to the dentist as well as to the physician and conveys to both a lesson worthy of remembrance.

Edinburgh.

A CASE OF TYPHOID FEVER WITH PROLONGED INCUBATION

BY W NORWOOD EAST M.D LOND, M.R.C S ENG, L.R C P LOND

DEPUTY MEDICAL OFFICER, H.M S CONVICT PRISON, PORTLAND
